AT the annual meeting of the St. Paul's Hospital for Diseases of the Eye and Ear several references were made to the new departure made in the direction of special measures for the treatment of ophthalmia neonatorum and the prevention of subsequent blindness. The scheme had been warmly commended in the memorandum appended to the report of the Committee of the British Medical Association, and had been there described as an almost ideal method which might well be imitated in other large cities. It was also stated that the Local Government Board had sent a request for particulars, and evidence had been given before the Parliamentary Committee appointed to consider the working of the Midwives Act. The cases treated in the hospital in the first year numbered 75, and in the first four and a half months of the present year 53. The ward now

contains 4 beds for mothers and 4 cots. The accommodation having proved insufficient the committee has appealed for funds to rebuild the hospital on a new site, opposite the David Lewis Northern Hospital. A special feature of the new hospital is to be the extra accommodation for children with a view to the prevention of blindness—work for which there is but scanty provision of beds in Liverpool. There will be an ophthalmic ward of 10 beds and 10 cots, and two wards (including isolation rooms) of 10 beds each for boys and girls respectively. It is proposed that this department shall be called the "George Edward Walker Memorial Children's Department," in memory of the late senior surgeon. It was stated that the cost of reconstruction of the hospital would be £13,000, of which sum £5,000 and the value of the land were already either promised or given. It was agreed to shorten the title to "St. Paul's Eye Hospital," and to cease to treat diseases of the ear.

Mr. Sydney Stephenson (Chairman of the Ophthalmia Neonatorum Committee of the British Medical Association) made an eloquent and convincing appeal for the prevention of blindness, on the grounds both of humanity and of economy. Besides those who appeared in the census as blind there were many persons of whom no official account was taken, whose sight was more or less permanently damaged. The cost of educating a blind child was ten times as great as the cost of educating a child with normal sight, and the result as to earning capacity was usually so much less that the blindness of each adult represented a loss of £50 yearly to the country. Nearly all cases of blindness in children were preventable. Cases of ophthalmia and corneal ulcer did extremely well in the country, and, though the committee had not at present any scheme for country beds, it would be a good thing if children's eyes were treated and their education attended to in the country. In the direction of curing ophthalmia neonatorum, St. Paul's Hospital had done pioneer work and set an example to the rest of the civilized world. As soon as a case was heard of, mother and child, with the co-operation of the local health authority, were removed to the hospital in an ambulance, so that they were not separated during the time the child's eyes were being treated. Of the 75 cases removed to the hospital last year 57 of the babies recovered full sight in both eyes. He did not hesitate to say that such a result would have been impossible with the older methods prevailing elsewhere. The public could rest assured that the money subscribed to the hospital would be well spent, whether the expenditure was regarded from a humanitarian or an economic point of view.

BIRMINGHAM.

BIRMINGHAM MEDICAL BENEVOLENT SOCIETY.

THE eighty-seventh annual meeting of the members of the Birmingham Medical Benevolent Society was held on May 25th. The report showed that there were twenty-five annuitants on the books at the end of the year. The annual value of the grants ranged from £18 to £36, and the sum expended in this way during 1908 was £757.

The following typical cases show the good work the society is doing:

Widow, aged 71, of M.R.C.S.Eng., L.S.A. Only income derived from the interest on £200. Granted £27, and has received already £930.

Widow, aged 48, of M.B., C.M.Glasg. Income £58. Has had to educate four children, the eldest is now 21. Granted £36, and has received already £381.

L.S.A., aged 70. Unable to work and has a wife dependent on him. One of his children gives slight help. Granted £36, and has received already £381.

Widow, aged 67, of M.D. Very small income, in bad health, in lodgings, and helped by her sons. Granted £36, and has received already £1,011.

L.S.A., aged 83. No income. Wife's friends are helping to support him. Granted £25, and has received already £112.

L.S.A., aged 57. Only income £60. He has a wife and nine children, only one of whom is independent. He is incapacitated from work. Granted £36, and has received already £54.

The invested funds of the society amounted to £15,940, making, with a balance of £120 at the bank, a total of £16,060. The income for 1908 was about £775, which was made up in the following manner: Members' subscriptions, £225; interest on investments, £535; donations, £15. The expenditure was £805, so that there was, for the first

time in the history of the society, an adverse balance of £31. The total number of benefit members at the end of the year was 390. The society lost six members through death during the year, and among these was Dr. Edwin Rickards, who was twenty-three years a director, eight years a trustee, and in 1906 president. Sir Thomas Chavasse was elected president, Dr. Simon president-elect; Dr. Langley Browne, of West Bromwich, and Dr. Kauffmann, of Birmingham, vice-presidents; Sir Thomas Chavasse, Mr. Bennett May, and Mr. W. Hewitt, trustees; Mr. F. Marsh and Mr. W. F. Haslam treasurers; Dr. Stacey Wilson and Sir Walter Fisher auditors; Mr. C. F. Crowder honorary solicitor; and Dr. Sawyer honorary secretary. The directors are Dr. Agar, Mr. W. Hewitt, Dr. Malins, Dr. Thomas Nelson, Sir James Sawyer, Dr. William Thomas, Dr. A. S. Underhill, Dr. E. E. Whitcombe, and Dr. Thomas Wilson.

THE CARE OF EPILEPTICS AND FEEBLE-MINDED.

The first annual report of Dr. B. Jordan, medical officer to the Moryhull Colony for Epileptics and Feeble-minded, recalls the fact that the object of the colony is that epileptic and feeble-minded persons under the care of the guardians of the parishes of Birmingham, Aston, and King's Norton should be placed under the most favourable conditions for their general well-being and improvement by residing in an industrial colony where special treatment, suited to their malady, could be provided. The medical officer reports that during the thirteen months the colony has been opened there has been a gratifying improvement in the general condition of the inmates. They were better in physical health, brighter in mental condition, more easily influenced by and amenable to the nursing staff, more capable of steady work, and more responsive to moral and mental impressions made on them by religious services and entertainments. The number of inmates was 94, and of these 55 were males and 39 females. A certain number of helpless epileptic and feeble-minded girls and young women were sheltered from the appalling evils which too often result from their being at large in poverty-stricken or vicious homes. Two men and three women died during the year, and fifteen men and fifteen women were discharged to union infirmaries.

WALES.

DOCTORS AND COLLIERS.

WE take the following from the *South Wales Daily News* of May 31st, with the explanation that the responsibility for the accuracy of the statements must rest entirely with our contemporary:

As the result of the refusal of the local Branch of the British Medical Association to extend by two months the notices to terminate their engagements given by the doctors at the beginning of the present month, the Llanbradach workmen employed at the local colliery at a mass meeting on Friday (May 28th) decided to start a medical fund of their own, and appointed a committee to take the necessary steps. The doctors, it appears, wish to secure the operation of the poundage system instead of the present one, by which every man and boy pays 3d. per week towards the fund. A recent ballot showed that 1,149 persons were in favour of the retention of the present system.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

THE Laboratory Committee, with the approval of the council of the college, has issued new regulations in the matter of reporting on specimens sent for examination. Formerly the corporation of the city paid an annual sum of several hundred pounds to the college for this work, but some years ago this honorarium was transferred to the John Usher Institute of Public Health of the University of Edinburgh. Despite the transference, the college laboratory has gone on doing this work for the medical profession, "all for love and nothing for reward." But now a new order prevails, and charges will be made varying from 2s. 6d. for examinations for tubercle bacilli, or for a culture from diphtheria swab and report, up to £5 5s. for a medical

report and culture for tubercle bacillus, or for an examination of the central nervous system of a dog suspected of hydrophobia. The examinations to be undertaken by the college laboratory cover a wide field—sputum, pus or other material, blood, hair, skin, urine, faeces, stomach contents, tumours, water, milk, hydrophobia, opsonic index, etc. The John Usher Institute of Public Health will continue to do the ordinary routine work for the general practitioner, such as diphtheria, tubercle bacillus, and the like.

EDINBURGH ROYAL INFIRMARY AND THE BUDGET.

At the weekly meeting of the managers of the Edinburgh Royal Infirmary on May 31st, Lord Skerrington presiding, Dr. R. McKenzie Johnston submitted a statement, made out on the basis of last year's figures, from which he showed that the increase in the duty on alcohol as proposed in the Budget would affect the institution to the extent of £112. This did not apply to alcohol as a beverage or as a stimulant except in a very small degree, but it applied to various preparations in which alcohol was largely used; anaesthetics alone accounted for nearly £50 out of this sum of £112. Dr. McKenzie Johnston had received a communication from Dundee Royal Infirmary, asking support to a movement to get some concessions in regard to the making of tinctures and other remedial preparations. In Dundee it was calculated that the Budget meant an increased expenditure of 10 per cent. Dr. Johnston was of opinion that it would be difficult to get exemption for hospitals alone. The matter was remitted to the Medical Committee for consideration and report.

THE REGISTRATION OF NURSES IN SCOTLAND.

The following is a copy of the resolution which has been sent to the Prime Minister on the subject of the registration of nurses in Scotland:

The Executive Committee of the Association for the Registration of Nurses in Scotland, at a meeting held in Edinburgh on May 14th, expressed their satisfaction that the Prime Minister was unable to assent to the proposals of the deputation which awaited on him on the 15th inst. This association (which represents public opinion, and, with a few exceptions, the opinion of the medical and nursing profession in Scotland) trusts that it will be afforded an opportunity of placing its views before any committee of the House of Commons that may be appointed to deal with this important subject. The enclosed printed statement (already published in the press) gives in detail the reasons of the association for objecting to Registration Bills No. 1 and No. 2, and although Scotland does not desire to be associated with the scheme of either of these bills, the Scottish Committee see no reason why a bill for the registration of nurses should not be introduced which would be satisfactory to England, Scotland, and Ireland, arranging for representative branch councils, and for a separate register for each country, to be embodied in one common register, the branch councils to supervise examinations in their own country, just as is done under the Medical Act, 1858, and its subsequent amending Acts. The views held by this association coincide generally with the recommendations of the Select Committee which reported to Parliament in 1905 on the question of State registration of nurses.

THE TREATMENT OF PHTHISIS IN EDINBURGH.

On June 1st the Public Health Committee of Edinburgh Town Council agreed to recommend that the number of patients suffering from phthisis, which the Committee has the power to treat at Colinton Mains Hospital, be increased from fifty to sixty-two, and that six pavilions should be provided for their use.

INDIAN MEDICAL SERVICE DINNER.

The annual Indian Medical Service dinner took place in the Caledonian Club, Edinburgh, on May 28th, and proved a marked success. Twenty-seven members, past and present, sat down, and the guests included the Presidents of the Royal Colleges of Physicians and Surgeons, Colonel Corker, R.A.M.C., Sir Halliday Croom, Drs. Haultain and McBride, and Lieutenant Bruce-Turnbull, 23rd (Sikh) Pioneers. The service was represented by Sir Alexander Christison, Bart., in the chair, Surgeon-Generals Bidie, C.I.E., Turnbull, K.H.S., Sinclair, C.S.I., and Hay, Colonels Warburton, C.S.I., Stephen, Arnott, MacLaren, Downie, Robb, Bannerman, Bell, Lamont, Wylie Thomson, and Julian Smith, Major Robertson-Milne, Captains McRae, Masson, Harvey, Stewart, Husband, Kirkwood, Roberts, Tarr, Fleming, and Morison.

After the usual loyal and patriotic toasts, the Chairman proposed in appropriate and eloquent terms, "The Medical Services," which was responded to by Colonel Corker. "The Scottish Universities" and "The Royal Colleges of Physicians and Surgeons, Edinburgh," was given by Surgeons-General Sinclair and Hay, and acknowledged by Dr. Allan Jamieson and Mr. Cotterill.

A most pleasant and enjoyable evening was spent, and before the meeting broke up, the health of the veteran chairman was proposed in the most felicitous terms by Colonel Warburton. This toast was received with the utmost enthusiasm, and all present were of opinion that this was the most successful I.M.S. dinner yet held in Edinburgh, and bestowed on Colonel Arnott full credit for all his work in organizing it.

THE FUTURE OF QUEEN MARGARET COLLEGE AS A MEDICAL SCHOOL.

The Universities Commission in 1892 empowered the Scottish Universities Courts to make provision for the instruction of women, either by admitting them to the ordinary classes or by instituting special classes. The latter course was adopted, as, with few exceptions, the professorial staff of that day did not desire to undertake the teaching of women, nor to admit them to their classes at Gilmorehill. Accordingly a full curriculum of medical studies was provided at Queen Margaret College under a special staff of lecturers and a few of the professors who were willing to undertake the double courses. The position became changed when new professors were appointed who were required to undertake the teaching of the women students. They soon felt it to be a distinct hardship that a special course of lectures were required for a mere handful of students, and a strong movement arose in favour of admitting the women students to the university classes, and eventually it was arranged that any individual professor could, if he wished, admit the women to his university class. This course was readily adopted, and already several of the Queen Margaret courses have been abolished. The most recent case is that of *materia medica*. Dr. Wm. MacLennan recently sent in his resignation from the lectureship at Queen Margaret College; it was decided that it would be inexpedient to appoint a new lecturer. Accordingly next winter the women students will be taught in the university. Already the following classes are held at Gilmorehill: Zoology, botany, physics, physiology, medical jurisprudence, and pathology. Probably when the new chairs for the final subjects are instituted at the Royal Infirmary, it will be found that part of the duties will include the teaching of women. From their point of view there is no doubt that the eventual abolition of the separate classes will be a decided gain in every way. They will obtain whatever advantage there is in being taught by their examiners, and there is no doubt that the Gilmorehill teaching facilities are on the whole greater than those provided at Queen Margaret College, where, with the exception of the special anatomical institute, the laboratory accommodation was very primitive. As a rule the number of women students was small—about a dozen each year—but the recent difficulty in Edinburgh has already increased the numbers.

PRESENTATION TO DR. JOHNSTON.

An interesting sidelight on late events at Ruchill is afforded by the presentation of a silver rose-bowl to Dr. and Mrs. Johnston by a deputation of the staff of Ruchill. The bowl bore the following inscription: "Presented to Dr. and Mrs. Johnston by the General Staff of Ruchill Hospital as a mark of esteem and affectionate regard, May 27th, 1909."

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

DUBLIN HOSPITALS BAZAAR.

The great bazaar in aid of the funds of Mercers' and the Orthopaedic Hospitals has been concluded. It was held in the magnificent buildings of the Royal Dublin Society, and was opened last Tuesday week by His Excellency the Lord Lieutenant and Lady Aberdeen.

It was favoured by good weather, a wide sympathy, and crowds of sightseers. In Ireland bazaars are popular, and every few years it is possible to conduct one on a scale of great splendour as this was. Every county had a committee, and there were elaborate stalls, cafés, and dancing halls, and the other arrangements which are essential to the success of such an undertaking. It is hoped that a substantial addition has been made to the hospital funds. About 50,000 persons passed the turnstiles in five days.

IRISH MEDICAL ASSOCIATION.

The annual general meeting of the Irish Medical Association will be held in Sligo on Tuesday, June 8th, when the chair will be taken by Sir William Smyly, President of the Association.

Special Correspondence.

VIENNA.

Morbidity and Mortality in Vienna.—Food of the People of Vienna.

THE report of the Board of Health for 1908 contains some very interesting figures regarding the public health and mortality in this city. The general health is improving, and the expectation of life has been steadily increasing since 1873. The number of deaths in the past year was a little over 35,000, or about 17 per thousand, with a population of two millions. But an analysis of the causes of death gives a good illustration of the importance of infantile mortality in the records of large cities. More than 27 per cent. of the deaths are those of infants under 1 year of age, while 8 per cent. are those of children from 2 to 5 years, so that about one-third (32 per cent.) of all persons who died belonged to the lowest age. Twenty-five years ago 38 per cent. of the deaths came under this heading. The constant remarkable diminution of infant mortality is a most gratifying feature of the modern endeavours to reduce the loss of young lives—*gouttes de lait*, mothers' associations, free milk distribution. As regards the causes, tuberculosis is responsible for 19 per cent. of the total number of deaths, infectious diseases for 11 per cent.; disorders of the intestinal canal, excluding neoplasms, caused 7 per cent. Only 29 persons died of typhoid fever (forty years ago typhus was an every day affection), thanks to the splendid water supply of Vienna. All cases could be traced to a source outside the town. Brain disease and neoplasms were rather less fatal last year than a few years ago. This, however, may be accidental. Special attention has been paid to diphtheria. The number of cases does not vary considerably, but the mortality has been found to be less than 10 per cent., even in hospitals, where only serious cases are received. The absence of deaths from small-pox is also noteworthy; nearly the whole population, with insignificant exceptions, is now vaccinated, thanks to the scare in 1907. On the whole, the health of Vienna is fairly satisfactory, especially as the tendency to improvement is steady.

For about two years the nature of the daily food of the people of Vienna has altered appreciably, partly from a change of taste, partly from an increase in the price of various articles of food, especially meat. The latter has become more than 30 per cent. dearer, when compared with 1902, and it is still going up. The report of the market board shows that there is a decided fall in the sale, and therefore consumption, of beef, whilst pork is more favoured. On the other hand, the increased consumption of eggs, potatoes, milk, and flour shows that large numbers of the population have adopted a more vegetarian mode of life. It may be doubted, however, whether this is done from any other reason than economy. The conditions are manifest enough to arouse public attention, and a deterioration of the national physique is justly feared. Therefore all public corporations have taken up the matter, and Government and municipalities are asked to bring about a change of the present policy, which makes the poor man's meat and bread dear, without enabling him, by better pay, to procure it in sufficient quantity for his family. The "anti-agrarian" movement is spreading fast, and it is hoped that it will succeed in bringing ordinary food once more within the reach of the consumer.

Correspondence.

THE DOCTOR AS A VICARIOUS PHILANTHROPIST.

SIR,—I have at different times and in divers places urged on my professional brethren that if they take up a determined stand they will secure that recognition and reward for their professional services to which they are entitled.

Here is a case in point:

At 7 o'clock last night a group of men brought a boy into my surgery, saying he had been run over by a cab. I asked of them, "Who guarantees to pay my fee for attending to the boy?" There was no answer. I then asked the cabman if he would not guarantee my fee on behalf of his employer, and he declined to do so. I then ordered the boy to be taken to the infirmary. The boy was taken away, and a hostile and threatening crowd gathered outside my surgery, cursing me for not attending to the accident. Five minutes later the boy was brought back by two policemen, and I said, "I refuse to attend, unless my fee is guaranteed."

One of the policemen said he would do so on behalf of the police, whereupon I attended to the boy. When the crowd and the boy had gone, the police remained to get particulars of the injuries.

In the course of the conversation I referred to the readiness of the public to call on the doctor for his help and of their unwillingness to pay the doctor's fee, and I was staggered to learn that the supposed cabman whom I asked to guarantee my fee in the first instance was the owner of the cab and the son of a large hiring proprietor.

The fee I shall get is a very small one, no doubt, but I have done a great deal for the vindication of a principle, upon which I wish more of my professional brethren would act. We have all suffered from being called to accidents, in having our clothes destroyed and our convenience set at naught; and when we have given freely of our physical powers, our professional skill, and our lint and bandages, we have all been turned into sad philosophers when liability was repudiated all round.

The payment of the doctor for street accidents is but a small phase of the social question which could be so easily settled, but which never will until the profession is united.

—I am, etc.,

Glasgow, May 27th.

J. WISHART KERR.

RURAL DISTRICT NURSING ASSOCIATIONS.

SIR,—The attention of the Chairman of the Central Midwives Board having been drawn to a letter signed "G. P.," appearing on pages 1153 and 1154 of your issue of May 8th, the letter was considered by the board at a meeting held yesterday.

I am directed to inform you that the board is prepared to investigate the matter if the writer of the letter will communicate with me.—I am, etc.,

G. W. DUNCAN,

Secretary.

Canton House, Westminster, London, S.W.,
May 28th.

PAYING PATIENTS AT VOLUNTARY HOSPITALS.

SIR,—It is to be hoped that this subject will receive careful consideration before the Association is definitely committed upon it, for it is of great importance to a large section of the public, no less than to those members of the profession who are attached to public hospitals.

The resolution passed by the Liverpool and Birkenhead Joint Divisions, as reported in the JOURNAL of May 29th (SUPPLEMENT, p. 327), disapproves of the practice of treating paying patients at public hospitals because it is wrong in principle and unjust. If it were true that hospitals compete with private nursing homes by charging the same fees or lower ones to those who can afford to pay more, the principle would be wrong indeed. But what does really take place is that patients who require treatment at an institution and whose means do not allow them to go to a private nursing home but who on the other hand are not poor enough to claim charity make use of an arrangement which is a great convenience to them while causing no loss to the hospitals. The arrangement may be regarded something like that upon which are based self-supporting

philanthropic institutions, and only proves once more the great necessity there is for self-supporting public nursing homes. Whilst the rich and the very poor are amply provided for, the great middle-class is left to look after itself—and it generally looks in vain.

As to the medico-ethical aspect of the matter, one fails to see why one should not be paid for one's services rendered to a patient under circumstances intended in the first instance for his—the patient's—convenience, provided, of course, the patient is willing and able to pay for them.

That the usual medical attendant is thereby deprived of fees which would go to him if the patient were debarred from deriving great convenience is hardly an argument which the profession can bring forward with any dignity. If any one has to wait for the realization of those "economic laws which regulate the matter of demand and supply," it must be the doctor and not the patient. Meanwhile it may be mentioned that there are many hospitals which have general practitioners on their staffs, and that the "usual medical attendant is not always deprived of his fees" when paying patients are treated at public hospitals.—I am, etc.,

Manchester, June 1st.

J. DULBERG, M.D., J.P.

THE ASSOCIATION.

SIR,—I notice Dr. John R. Hamilton's letter in the JOURNAL (p. 1331) commenting on a passage in the Report of the Council of the Association regretting that the "increase in the membership was not more marked," etc., and attributing that fact to the splitting up of the Association into Divisions.

I attribute it to another fact. I find that the usual reply I get when asking some one to join the Association is "What has the Association done for us?" This is an example of the old adage, "Give a dog a bad name and hang it." The Association got its bad name in the old days, when it simply held "pleasant meetings with items to interest and amuse," and when the medical practitioners of the country were wanting it to attend to their real interests, and it did not at all, or only scantily. It has not had time to lose that bad name yet, and if it is to lose it its members must be more earnest in their attendance at its meetings, and in giving proper instructions to the delegates they send to the Representative Meeting. The members have now the success of the Association in their own hands, and will mar or mend it accordingly as they perform their duty towards it.—I am, etc.,

Ashton-under-Lyne, May 29th.

SAMUEL CRAWSHAW.

THE PROFESSION, THE ASSOCIATION, AND THE JOURNAL.

SIR,—The object of the existence of the British Medical Association may very largely be expressed by the late Mr. Ernest Hart's rendering of a famous dictum: The government of the profession, by the profession, for the profession. It is clear that this object can only be attained by the absorption into the Association of the very large number of men who still remain outside its ranks. I have not the exact figures, but I think that at the present moment something over half the total number of medical men in the United Kingdom are members.

Dr. Brown, of Baeup, informs me that, in the fifteen Divisions of the Lancashire and Cheshire Branch which make returns both of membership and of the numbers of medical men practising within the areas of the said Divisions, there are 716 members out of a resident total of 1,367. Assuming, then, that two-fifths of the profession in these islands are still outside the ranks of the Association, it is clear that the latter cannot speak with all the authority of the profession as a whole. Only a few days ago, at the interview of a representative deputation with the Prime Minister enent the State registration of nurses, the fact that the British Medical Association is far from being in a position to speak for the profession as a whole seems to have been urged with a view to belittling the objects of the deputation.

Now, can anything be done to close up the ranks of the profession, and to unite with us those who are still outsiders? After considerable consideration, and after discussing the matter with several members of the Association, I make bold to say that the JOURNAL, which up to a certain point has been the making of the Associa-

tion, is now the greatest bar to our further progress. I have little doubt that this statement will be derided in many and influential quarters. But I feel convinced that a very large number of men would join our ranks but for the fact that doing so involves subscribing to a medical periodical which they either do not want or have other opportunities of seeing. In saying this, I do not for a moment wish to disparage the conduct of the JOURNAL, which holds a place of high honour among the medical periodicals of the world. But it is inevitable that among many thousands of medical men there must be many who would prefer some other periodical.

I venture, therefore, to take the liberty of calling attention to the resolution of the Rochdale Division, published in the SUPPLEMENT of May 8th, 1909, p. 236, suggesting that there be in future two grades of membership subscription, one, as at present, to include membership and JOURNAL, the other (say 10s. 6d. per annum) to include membership and the SUPPLEMENT only. Our Representative has been instructed to bring this forward at the Belfast meeting.

The advantages which I believe would accrue from this change are, in my opinion, mainly two:

1. A large accession of new members. This is infinitely of more consequence than any mere increase in the circulation of the JOURNAL.

2. It would at once clear the way for the absorption into the local Division of the Association of a large number of local medical societies. This is most desirable, as in many instances there is not room for two medical societies in areas which are nearly coterminous.

It is possible that some subscriptions might be partly lost through present members taking advantage of the lower grade of subscription. This, however, would be a small price to pay for the advantages.

I suggest that the machinery of the Association might be utilized to ascertain the views of non-members in respect of some such scheme as I have attempted to outline.—I am, etc.,

Rochdale, June 1st.

J. CUTHBERTSON WALKER.

SANITARY PROGRESS IN THE BRITISH WEST INDIES.

SIR,—I have just returned from a special visit to Barbados, St. Vincent, St. Lucia, Grenada, British Guiana, and Trinidad, having been especially concerned with mosquito-borne diseases, more particularly yellow fever.

I have read the official report of a committee which was established in 1852 to inquire into the terrible mortality, chiefly from yellow fever, amongst the military and naval forces then stationed in the West Indies. The appalling picture of death and loss of money at that date and the comparative health-security of to-day shows that immense strides in prophylaxis have been made. These I have carefully analysed, and I am now in a position to state that, certainly since the date of my visit to British Honduras in 1905, a most energetic campaign has been undertaken against mosquito-borne diseases. In the first place, the doctrine of mosquito-borne diseases has taken root. Of course there are a few fixed individuals yet to be found amongst our own profession, as well as amongst the legal and business men; but taken as a whole, the people have learnt. I am in a position to state this, for during my visit I delivered 32 addresses to all classes of society, examined 1,097 yards and 2,292 water receptacles. This splendid advance in knowledge has been brought about by means of lectures and cheap literature in the form of pamphlets, diagrams, circulars, notices, and primers used in the schools. To show how real the movement is it is now a punishable offence to have larvae on premises, and no less than 226 summonses have been taken out since 1907, and fines inflicted from 1s. to 40s. During the last three months there has been a remarkable increase of activity. Yes, the people now understand, "No *Stegomyia*, no yellow fever." "No *Anopheles*, no malaria." Indications also are not wanting that the profession is realizing the advantage of uniting for the purpose of advancing medicine by reading and publishing papers of value. I had the honour of addressing several meetings of Branches of the British Medical Association, which have been formed in the islands; but much more in this direction requires to be done. Whilst on this topic, I venture to suggest that a meeting of the British Medical Association in Trinidad

or Jamaica would do much to stimulate medical and health progress in our West Indian Empire, and would be most popular and easily organized. Finally, it was my good fortune to fall in with the work of Dr. Beaupertuy, who, born in Guadeloupe, flourished in Cumana in Venezuela, and died in British Guiana. To him belongs the credit of having to my mind foreshadowed the doctrine of insect-borne disease. His opinion on yellow fever and malaria are strikingly prophetic, and his fulminations nearly one hundred years ago against the absurdity of "miasm"-borne diseases have to-day been proved to be fully warranted.—I am, etc.,

University of Liverpool, June 1st.

ROBERT BOYCE.

* An account of Beaupertuy's life, work, and opinions was given in the JOURNAL about a year ago (May 30th, 1908, p. 1306), and will be read with interest in connexion with Sir Robert Boyce's letter.

OPERATIONS ON THE PROSTATE.

SIR,—May I make some remarks upon the case of enlarged prostate described by Mr. Fullerton in the JOURNAL of May 22nd? The estimation of prostates by weight is convenient, sufficiently accurate, and serviceable for statistical purposes. To the operating surgeon it is of little use, because it gives little if any idea of the mechanical difficulties of operation which depend much more upon such properties as size, shape, consistence. From a general point of view, I think it is of still less service, for, while to surgeons accustomed to see, handle, and weigh prostates, their weight may give an approximate notion of their size, it can give none of their other qualities; while to those not actively engaged in operating on prostates it gives practically no concrete notion at all.

From Mr. Fullerton's account of the case, it is clear that before beginning the operation he did not expect to find any particular difficulty, whereas, in fact, extreme difficulty was experienced. I would ask whether examination immediately after the bladder was opened gave any indication, and if so what, of the degree of difficulty likely to be found.

The adoption of a line of treatment by a man of Mr. Fullerton's professional attainments and position cannot be without influence. I therefore venture to offer the following comments because I think the account of the case given shows that the treatment adopted was not the wisest.

For ten years before operation there was nocturnal micturition—cause not stated, presumably not known at the time, reasonably to be regarded as enlarged prostate. Nine months before operation there was brief spontaneous haematuria with gravel, and the prostate was found to be enlarged—cause of haemorrhage not stated, presumably not definitely known, possibly gravel. Two days before operation slight haematuria occurred—cause not stated, presumably unknown. On the day before operation there was retention of bloody urine, relieved by catheter; and on the day of operation there was retention of urine containing clots, relieved by suprapubic puncture—cause not stated, presumably not known.

Operation was rightly considered, and now, I submit, the first mistake was made. It is clear that the most urgent indication was to relieve retention. The catheter had failed; the aspirator had given temporary relief. It is not stated that clots had come away; presumably they were still in the bladder. There is no mention of any sign that the bleeding was diminishing.

The second indication was to check the vesical haemorrhage. The most promising way to fulfil these two indications, in view of the known large size of the prostate, was to open the bladder above the pubis. There is nothing in the account of the case to suggest that the fulfilment of these two indications would not restore its former degree of efficiency to the bladder, a condition, I submit, by no means amiss in a man of 73. This patient had had a grave cardiac attack ten days before, and this, together with his age, made it clear, I think, that the less that was done consistent with relief the better; while the short duration of the urgent symptoms suggested the probability that relief might have been simply obtained.

Notwithstanding these facts and the misgivings which they occasioned prostatectomy was the only operation stated to have been considered. This, I think, was bad.

Prostatectomy was the operation performed, which, I think, was worse. Prostatectomy was the operation which the patient just managed, with help, to survive.

Only in the last sentence of the report of the case is there to be found any reference—and that a passing one—to what seems to me the key of the clinical picture.

I submit, with all deference to Mr. Fullerton's much greater experience, that the indications in this case, as recorded, were these:

1. To empty the bladder, because retention existed.
2. To do this by cystotomy, because the catheter had completely failed and the aspirator had not removed clots.
3. To open the bladder above the pubis, because of the ascertained great size of the prostate.
4. To decide upon further measures after the interior of the bladder had been explored, because the condition of its interior was very incompletely known.
5. Having opened the bladder above the pubis and found, as described, a large prostate and a mulberry calculus, to remove the stone, wash out, and drain the bladder.

I think that the sufficiency of this treatment is indicated by these considerations: the presence of the mulberry stone was sufficient to account for the haemorrhage described; the prostate, despite its great size, had not of itself caused much trouble; its immediate removal, therefore, was not necessary, and might—and in the event did—involve an enormous strain upon the patient.—I am, etc.,

Middlesbrough, May 25th.

ROBERT K. HOWAT.

HYPODERMIC INJECTION OF STRYCHNINE.

SIR,—Mr. Charles Randolph raises an interesting question in his letter in the JOURNAL of May 29th, p. 1331. It is especially so in view of the modern tendency among physiologists and surgeons to decry the value of hypodermic injections of strychnine. Quite recently, in a paper on the treatment of shock during anaesthesia, read before the Anaesthetic Section of the Royal Society of Medicine, Dr. Dudley Buxton deprecated the injection of strychnine. To me these pronouncements come somewhat as a surprise. Twenty years in general practice and ten in that of anaesthetics have convinced me of the value of strychnine injections in suitable cases. Of course, it is useless to expect good results when the patient is almost pulseless, as the drug probably never gets into the circulation. But when the circulation has not sunk quite so low as this, or there is a chance of reviving it by artificial respiration, oxygen, or intravenous saline infusion, my experience is that injection of a full dose of strychnine is most valuable.—I am, etc.,

London, W., May 29th.

G. A. H. BARTON.

THE CAUSATION OF CANCER.

SIR,—Will any of your readers kindly offer arguments against or in favour of the following reflections on the causation of cancer?

That chronic irritation is the safest "jumping-off place" for cancer research, there being no doubt as to the important part which such irritation plays in the development of cancer.

That the evidence so far adduced is in favour of a verdict of cancer from natural causes. That what we call Nature or the mysterious forces contained in cells which Weismann calls "determinants"—having tried in vain to heal a chronically inflamed wound in a position where the necessary physiological rest is impossible, and in a person with enfeebled nerve force and devitalized tissues, has recourse to another plan—namely, changes the original destiny of the local cells and resuscitates ancestral reproductive faculties. That this influence of irritation on specialized cells is quite in harmony with the doctrines of evolution, and a cell with reproductive faculty might very well get into the lymph stream and start secondary growths in the glands or elsewhere.

From a fragment of a begonia leaf may arise an entire individual capable of continuing the race. Environment here changes the destiny of the cells. Among low multicellular types, the power of continuing the race persists in many cells, and environment decides whether it shall be exercised or not. The power of regeneration in specialized tissues is only lost because the retention of the power is no longer useful.

That as regards reaction to environment, a plant and a

man must be placed in the same class. Of interest in this connexion is Darwin's remark that "if a flower is accustomed to open at sunrise it will open none the less punctually if transplanted to a dark cellar. A residue of the stimulus remains in the cells so that opening at a given time becomes part of its being."—I am, etc.,

Lightcliffe, nr. Halifax, May 29th.

ASHNALL MARSDEN.

Obituary.

SIMEON HOLGATE OWEN, M.D., M.R.C.P.,

CONSULTING PHYSICIAN, MANCHESTER NORTHERN HOSPITAL.

Few men of a retiring disposition will be so much missed by a large circle of friends as Dr. Simeon Holgate Owen, who died suddenly from heart failure, after doing an ordinary morning's work, on May 19th, at his residence, Whalley Range, Manchester. Dr. Owen was in his 65th year, and for some years had suffered occasionally from pains in the chest which were apparently regarded as dyspepsia, so that his death came with quite unexpected suddenness. He was the son of the late Mr. Henry Owen, Dental Surgeon, and obtained the diplomas of M.R.C.S. and L.S.A. in 1869. He graduated M.D. at Queen's College, Belfast, in 1872, and obtained the M.R.C.P. Lond. in 1888. For some years before the incorporation of Moss Side, Manchester, he was M.O.H. for that district, and was a Fellow of the Royal Institute of Public Health. At that time he took special interest in sanitary science, and frequently lectured on public health subjects for the Manchester and Salford Sanitary Association, of which he was an active member. Two of his lectures on Fevers, their Nature and Prevention, and Work and Recreation in their Relation to Health, were published, and were very favourably received. He had held the posts of Assistant Physician to the Manchester Royal Infirmary and House Surgeon to the Manchester Southern Hospital for Women and Children. He was best known, however, as Physician to the Manchester Northern Hospital for Women and Children, a post which he held for some years and where he endeared himself to a large number of patients by his careful, painstaking, and sympathetic treatment. On his retirement from the active work at the Northern Hospital he was elected consulting physician, his services to the hospital being as much appreciated by his colleagues and the Board of Management as by the patients under his care.

For many years he took a very active part in the work of the various medical societies in Manchester. In 1891 he was President of the Clinical Society, and in 1893-4 Vice-President of the Manchester Medical Society, of which he was elected Honorary Treasurer in 1903. He also held the position of President of the Medico-Ethical Association on two separate occasions, having been elected for the second time shortly before his death. For some time he made diseases of the heart a special study, and wrote various articles on the subject, among which may be mentioned *Mitral Disease in Children*, *The Prognosis of Mitral Disease in Children*, and *Cardiac Thrombosis after Abortion*. He was also the author of numerous reviews and articles on general literary subjects. He was an enthusiastic Unionist, and a member of the Manchester Constitutional Club, and worked hard, if unostentatiously, for his party.

As a member of the British Medical Association he took no active part until comparatively lately, but as a member of the committee recently appointed by the Joint Divisions of Manchester and Salford to consider the ethical relations between consultants and general practitioners in Manchester he showed an amount of fair-mindedness and sympathy with both branches of the profession that augured well for the success of the committee in its difficult task. Shortly before his death he was elected Chairman of the Manchester West Division, and the Honorary Secretary of that Division writes as follows: "As one who has enjoyed the privilege of frequent personal intercourse with the late Dr. Holgate Owen, and has often benefited by his ever ready sympathy and help, I feel, and all who knew him will agree with me, that his Division has lost in him an ideal chairman and a true friend. Although in the past

he had been unable to take any active part in the work, he was keenly alive to, and showed much interest in, what was done, and he was ever willing to aid with well-considered advice. Dr. Owen was unanimously elected to the chairmanship of the Division for the ensuing year at the annual meeting on May 11th, and a day or two later wrote accepting the position and expressing his pleasure at the prospect of active work in the interest of the Association. He promised to attend the first meeting of the Executive Committee, but he died on the afternoon of the day previous to the meeting. The news of his sudden and unexpected death came as a rude blow to the hopeful anticipations of a year's pleasant labour under his able leadership, and added to the bitterness of the personal loss felt by those who reckoned him among their friends. The geniality and earnestness so characteristic of him, his courtesy, tactfulness, and common-sense methods of dealing with difficulties, and his general popularity—he had no enemies—all tend to make the loss of such a man seem wellnigh irreparable, alike to his Division, his profession, and his personal friends."

MR. JOHN MASON WILLEY died at his residence in Leicester on May 20th after a prolonged illness. He was born in 1852, and received his medical education at St. Bartholomew's Hospital. After obtaining the diploma of M.R.C.S. Eng. in 1876 he spent several years in resident appointments. He was House-Surgeon successively to the Jessop Hospital for Women, Sheffield, the Sheffield Public Hospital and Dispensary, and the Royal Isle of Wight Infirmary, Ryde. In 1883 he became L.R.C.P. and L.M. Edin., and in 1890 he settled in Leicester and was engaged in busy general practice until failing health compelled his retirement in 1908. Of quiet and retiring disposition, Mr. Willey's kind, unassuming manner made him very popular among a large circle of patients. For several years he held the post of Surgeon to the Leicester Provident Dispensary. Mr. Willey leaves a widow, but no family.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are: Professor Guldstrand of Berlin, a well-known medical statistician, aged 70; Dr. Vicente de Figueiredo Saboia, formerly Professor of Clinical Surgery in the Medical Faculty of Rio de Janeiro; Dr. Paul Cavaillon, *agrégé* Professor at the Medical Faculty of Lyons, and founder of the *Lyon Chirurgical*, aged 32; Dr. Ernest Besnier, Member of the Paris Academy of Medicine, one of the most famous dermatologists in Europe, sometime head of the Dermatological School of Saint Louis Hospital, founder of *Annales de Dermatologie*, author of numerous works on general medicine and hygiene, as well as dermatology, and translator of Kaposi's *Lectures on Diseases of the Skin*, with copious notes; Dr. Manuel Amador, first President of the Republic of Panama, and at one time the leading physician on the isthmus, aged 74; and Dr. Ferdinand Klug, Professor of Physiology in the University of Budapest, aged 64.

THE LATE PROFESSOR GERALD YEO.—In the obituary notice of Professor Gerald Yeo, published in the *JOURNAL* of May 8th, it should have been stated that Professor Yeo left only one son, who is a second lieutenant in the Devonshire regiment.

Medico-Legal.

HERBALISTS AND THE PEOPLE.

AN inquest was held in Sowerby on May 17th on a woman whose death would appear to have been due to internal strangulation, which being unrelieved was followed by peritonitis. She fell ill on May 6th, and died a week later. Two days after she began to be ill a herbalist named Culpan was called in to attend her, and continued to do so until she died. Late on the night before her death a medical man was asked to see her, but sent a message to the effect that he would be unable to come that night. The jury returned a

verdict of death from natural causes. Culpian was not present at the inquest, but subsequently wrote a letter to the *Halifax Guardian* saying that on the morning of the day he first visited the deceased he was asked for a mixture to stop "bilious vomiting," but declined to give it until he knew more particulars. In the afternoon he diagnosed the case as one of inflammation of the bowels, probably complicated by peritonitis. The following day he confirmed his diagnosis and suggested that other advice should be summoned, but the patient declined and asked him to continue to treat her. This letter was written subsequent to the holding of the inquest and to the medical evidence as to the nature of the disease and the cause of death.

The case in its essential features is merely one more unfortunate instance of a person trying owing to causes which could probably have been removed had medical attention been received, but the action of the jury on the occasion lends it a certain special interest. The foreman and other members of the jury kept on arguing with the coroner as to why the inquest should have been held at all, and evidenced a strong desire to defend Culpian—who was mentioned as "Dr." Culpian from any kind of blame. They had known him for thirty or forty years and had every confidence in him. He was not a mere quack—not a person continually coming and going—but one who had been brought up among the people, and a very respectable man. The chivalry thus displayed is a pleasing feature which might well be emulated by juries elsewhere; but, on the other hand, the jury's general attitude towards the matter did little credit to their heads. The only excuse that can be made for them is that subsequent events seem to show that they were under the influence of an egregious body calling itself the National Association of Medical Herbalists. Its members wish the people to believe that an elementary knowledge of herbs administered by rule of thumb is all that is required for success in the treatment of sickness, and to conceal from them the fact that when they consult a medical man they receive advice founded not only on a complete knowledge of the laws, but of the human body and its diseases as well. As Yorkshiremen, but the reputation of being curers, one would not have imagined that these Sowerby people would have been thus deceived, or have failed to see for themselves that the cheapest goods to buy are those into which the most labour has been put.

It is to be feared, however, that nothing will prevent the occurrence of preventable deaths of the same kind until the Legislature places a penalty on the practice of medicine by persons who have no scientific knowledge of it.

WORKMEN'S COMPENSATION CASES.

Refusal to Undergo an Operation.

ALTHOUGH a workman may be justified in refusing to undergo an operation, the county court judge has it in his power to reduce compensation if the workman will not submit to reasonable treatment. In a case at Barnsley, a man who had sustained an injury to his right finger was awarded compensation at the rate of 15s. 10d. a week. It was suggested by the employers that an operation would enable him to work. The man, however, refused to undergo the operation, as his medical adviser recommended him not to. He had neglected, however, to have the hand massaged. The county court judge held that while the refusal to be operated on was justifiable, the workman had not done all that he could to get his hand better. He therefore reduced the compensation to 12s. 10d. a week.

Carbolic Acid Poisoning.

It is for those who make claims under the Act to prove that the death or injury was caused by accident. In a case at Manchester a cloth presser died of carbolic acid poisoning. It was proved that this fluid was used in the works, that the deceased was in the habit of drinking his tea out of mineral water bottles, and that a bottle containing traces of carbolic acid was lying near where the deceased lay. Upon this it was suggested that he must have been killed by drinking something which he thought was harmless. The judge held that no case had been made out.

Probable Future Incapacity.

The fact that a workman may at some future time suffer incapacity as the result of an injury is a matter which the court will take into account when asked to make a declaration that liability is at an end. In a case heard in Scotland a man had sustained a rupture while lifting a derailed hatch. He returned to work in three weeks at full wages. In a claim for compensation he only asked for three weeks' wages, but he also sought a declaration of liability. The sheriff decided, on the medical evidence, that as there might be incapacity at some future time in consequence of the injury, the workman was entitled to have his right to prefer a claim kept alive.

Medical Notes should be Taken.

At Merthyr, during the hearing of a claim, it was pointed out that the number of claims that went into court was very small compared with the number with which doctors had to deal. The judge remarked that he would look with some suspicion on the evidence of medical men who made no notes on such cases. It was almost impossible for them to remember one case out of a hundred, and it would only take a minute to make a note at the time.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

THE following degrees were conferred on May 27th:

M.D.—R. E. French, King's; J. C. L. Roberts, Cla.; F. W. M. Palmer, Jes.
M.B., B.C.—F. C. Trappell, King's; J. W. B. Bean, H.-Selw.
M.B.—S. Maclaren, Trin.; F. Worthington, Joh.; G. H. Davy, Govt. and Cal.

UNIVERSITY OF LONDON.

THE following candidates have been approved at the examinations indicated:

FINAL M.B., B.S.—A. H. G. Burton (c), Guy's Hospital; "R. R. Elworthy (a), Westminster Hospital; A. P. Fry (d), St. Bartholomew's Hospital; "M. D. D. Gilder (c), University College Hospital; "C. A. Joll, B.Sc. (a, b, c, d), University Medical, University College, Bristol; "D. A. Powell (a), Charing Cross Hospital; J. T. Baker, S. J. A. Beale, T. L. Bonford, R. H. Bott, K. Bremer, C. H. Broadhead, J. P. Buckley, Elsie M. Chubb, L. Croft, S. J. Darke, H. C. R. Darling, T. B. Davies, N. C. Davis, G. V. Deshmukh, Irene C. D. Eaton, A. E. Evans, T. Evans, C. H. S. Frankau, W. L. E. Frez, Janet M. Fiske, H. S. Furness, C. J. Galbraith, H. Gooch, A. E. Jow, F. N. Houghr, E. R. Holborow, M. J. Holgate, W. F. Holtbusen, H. P. L. Hurst, Melville Hunt, J. L. Johnston, E. J. G. Jones, R. P. Jones, W. B. Jones, J. D. Judson, H. C. Lucey, G. R. Lynn, J. C. Lyth, H. E. H. Mitchell, M. H. E. R. Montesole, H. L. Morgan, W. P. H. Munden, W. H. Palmer, O. B. Parry, J. R. Pordran, Ellen M. Pickett, Laura G. Powell, T. E. Pryce, W. P. Purdon, R. A. Rankine, H. A. H. Robson, J. E. Scudamore, Florence Stacey, Marione Stocks, St. J. A. M. Tolhurst, S. A. Tucker, J. O. D. Wade, H. G. Willis, C. A. Wood.

- (a) Distinguished in Medicine. (b) Distinguished in Pathology.
- (c) Distinguished in Forensic Medicine and Hygiene.
- (d) Distinguished in Surgery.

FINAL M.B., B.S. (Group I only).—E. W. Archer, B.Sc., Ella M. Barker, A. Burrows, D. F. Dobson, J. S. Lukis, W. N. Pickles, G. R. Strong, R. R. Vickers, G. R. Ward, H. O. Williams.
FINAL M.B., B.S. (Group II only).—Anne Borrow, W. F. Bowen, C. G. Galpin, W. S. Hughes, J. E. L. Johnston, D. Loughlin, P. D. F. Makovan, J. H. Meers, L. G. S. R. Oxley, A. H. Peniston, S. G. H. Salmond, F. C. Seale, R. H. Smith, W. R. M. Turtle, L. A. Weakley, H. O. West, R. T. Williams.

UNIVERSITY OF DURHAM.

MEDICAL GRADUATES' ASSOCIATION.

Increase of Council.

AN extraordinary meeting of the association was held on May 28th at 11, Chandos Street, London, W., when Dr. R. A. Bolam's motion to increase the number of the Council from 12 to 13 was carried unanimously.

Annual Meeting.

At the annual meeting which followed, with Mr. Bruton Angus in the chair, it was decided that the auditors shall not be *ex officio* members of council.

The Treasurer's report was agreed to after some criticism on the way it was drawn up.

Dr. Braithwaite proposed that the method of voting for the election of officers should be entirely by ballot paper. It was agreed to refer the question to the Council for consideration, and the following officers were then elected: Wm. Rawes, M.D., F.R.C.S., President; T. Beattie, M.D., B.S., M.R.C.P., and M. G. Biggs, M.D., Vice-Presidents; Wm. Martin, M.A., M.D., B.S., and J. Inglis Parsons, M.D., M.R.C.P., Honorary Secretaries; eighteen members of Council, and three Auditors, Dr. Wm. Rawes, the President, and Drs. Wm. Martin and Allison were elected Representative Governors of the Court of the Durham College of Medicine. Dr. Edridge Green's motion that "Four members of Council shall form a quorum" was carried by a majority. The report of the Subcommittee on the University Bill was approved. Sir T. Lauder Brunton and Dr. W. F. Mott were unanimously elected honorary members of the association.

Annual Dinner.

The members and their guests dined together the same evening at the Café Royal. Dr. William Rawes, the new President, in the chair. The "University of Durham" was proposed by Mr. Bruton Angus, and responded to by Sir George Hare Philipson. "The Association" was proposed by Dr. F. W. Mott, and responded to by Dr. Inglis Parsons. The toast of "The Guests" was proposed by Dr. F. M. Saudwith, and responded to by Sir James Barr in humorous terms. Some excellent music was provided by Mr. A. E. Godfrey, and a most enjoyable evening was passed.

QUEEN'S UNIVERSITY OF BELFAST.

STATUTES MADE BY THE COMMISSIONERS.

THE statutes made by the Commissioners appointed under the Irish Universities Act, 1903, for the government of the Queen's University of Belfast were issued on May 22nd.

There are four Faculties—Arts, Science, Law, and Medicine.

In Medicine there are six degrees: the usual ones of Bachelor of Medicine, of Surgery, and of Obstetrics (M.B., B.Ch., and B.A.O.) constitute the primary degrees of the Faculty, and require five years' registration as a student of medicine and attendance in Belfast on the prescribed course of studies for three academic years at least. The degrees of M.D., M.Ch., and M.A.O. will not be conferred until the expiration of at least

three more academic years, or in the case of graduates of the university in Science and Arts, of two years. These latter degrees will be conferred after examination or submission of a thesis.

No mention is apparently made of State medicine or public hygiene, and considering the enormous importance of these studies, the great number of Belfast students that seek a degree or qualification in them from Cambridge, Dublin, and elsewhere, and the general public interest, this must be regarded as a grave omission. Neither is there any mention of dentistry, nor in the arts and science faculties is there word of commerce. The Commission may, of course, have found that these last two departments are not a success elsewhere.

Only the main outline or skeleton appears in these statutes, but there is a certain feeling of disappointment that when a new university was thus being forged red hot, the opportunity should not have been seized of beating the yet malleable form more into the state anticipated by the leading thinkers of the day. The old division between physician and surgeon is fading; gynaecologists are both, and answer the demand of facts. The day when the young surgeon will be taught asepsis and how to perform intestinal anastomosis and other abdominal operations in the veterinary wards and theatre seems not far distant.

The whole classification of medical science and art is changing. Every medical ward in a hospital seems to require a surgeon, and every surgical one an immunizer. It is to be hoped that the statutes are not final, and that liberty of expansion in both faculties and degrees may be given to the Senate. As at present drawn they offer no recognition of the great changes that are fast taking place in what may be called the very constitution of medicine.

UNIVERSITY OF BIRMINGHAM.

The Ingleby Lectures.

SIR THOMAS BARLOW delivered the first of the Ingleby Lectures on May 27th, in the Medical Lecture Theatre at the University to a very large audience. The subject of the lectures is Raynaud's disease and erythromelalgia, a summary and a review.

Public Health

AND

POOR LAW MEDICAL SERVICES.

URBAN DISTRICT COUNCILS AND THEIR MEDICAL OFFICERS.

THE answer returned under this head in the JOURNAL of May 22nd, p. 1275, was given under a misapprehension. It was thought that the inquiry referred to an appointment under the Poor Law, whereas it referred to an appointment of medical officer of health. As Dr. Butler-Hogan has pointed out, and as is, of course, well known, the General Order of the Local Government Board as to Medical Officers of Health and Inspectors of Nuisances (Urban Sanitary Authorities), dated March 23rd, 1891, contains the following, Article (3):

An appointment shall not be made unless an advertisement specifying the district for which such appointment is to be made, together with the amount of salary proposed to be assigned, and the day fixed for such appointment, shall have appeared in some public newspaper or newspapers circulating in the district of the sanitary authority at least seven days before the day so fixed.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Surbiton Urban District.—Based upon an estimated population of 18,747 persons, the birth-rate in 1908 was 20.5 per 1,000, the death-rate from all causes 10.4, and from zymotic diseases 0.4 per 1,000. The infant mortality-rate was equal to 70 per 1,000 births. The medical officer of health (Dr. Owen Coleman) points out that it is important to correct the crude death-rate by excluding non-residents who die in public institutions within the district and including residents who die outside the district. He appears to have been at some pains to make these corrections in his mortality tables, and complains of the difficulties which attend the gathering together of the necessary data. He expresses the opinion that there should be devised some machinery for forwarding the necessary information to the medical officer of health, and considers that the registrar is the person to whom the duty should be entrusted. We would point out that arrangements are already made by many medical officers of health under which the registrars supply the information desired by Dr. Coleman. It is true it is no part of the registrar's duty to make out the necessary returns, but as he is willing to furnish them upon being paid by the sanitary authority the usual fee of 2d. for each entry and for each return. Since 1898 the Surbiton Council have had power under a by-law to require the owner of a dwelling-house to pave a yard or open space in connexion with the house if it is necessary for the prevention or remedying of insanitary conditions. It is satisfactory to find that this regulation is being enforced, and that already nearly 500 houses have been satisfactorily dealt with. Many observers have commented upon the relation between outbreaks of diphtheria and unpaved back yards. It would be of interest to know whether the activity of the district council in the manner indicated in any way accounts for the lessened incidence of the disease in the town of Surbiton.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL.

THE offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL are at 429, Strand, London.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C. TELEGRAMS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Articulate, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONE (National).—

2531, Gerrard, EDITOR, BRITISH MEDICAL JOURNAL.

2530, Gerrard, BRITISH MEDICAL ASSOCIATION.

2534, Gerrard, MEDICAL SECRETARY.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

DESIGN OF SURGERY.

T., who is about to put up a surgery to be attached to his house at a cost not exceeding £60, would be glad to know what other medical men have found most suitable.

DENTAL FEES.

CARIES asks what would be a fair fee for a qualified dentist in a small town to charge an ordinary patient (clergyman) for refilling an incisor with gold, the time occupied being one hour and a half?

*. The question is difficult to settle, so much depending upon the class of practice and the standing of the practitioner. For protracted and difficult operations a dentist in high-class practice in London would charge a fee of 2 guineas an hour, and in some provincial towns fees nearly as high are obtained, though as a rule probably about half this fee would be regarded as a good one. It is to be remembered that the longer the operation the more gold is used, and the cost of the gold may be considerable.

LETTERS, NOTES, ETC.

"A CHRISTIAN SCIENCE LECTURE."

WE have received a letter from Mr. Frederick Dixon, who writes from the office of the District Manager of the Christian Science Committee on Publication for Great Britain and Ireland relative to a paragraph under this heading, which appeared in the JOURNAL of May 29th. It is too long to publish in full, but we give what seem to us the essential parts. After saying that our correspondent speaks of the cough of a lady beside him who had not attained sufficient faith to overcome it, he goes on:

Now, supposing this to be the case, what does it prove? Really nothing at all, since, for aught I know, in order to overcome the cough the lady might have had to overcome something very much more serious than a cold, and no Christian Scientist pretends to be able to overcome every phase of sickness instantaneously. But, as a matter of fact, how does he know that the lady was a Christian Scientist? The probabilities are distinctly against it. So many patients have been turned away from Dr. Munro's first lecture that Christian Scientists were largely conspicuous by their absence at the second, having left the hall mainly to the outside public.

Passing on now to his argument why, if Christian Scientists are engaged in ignoring the evidences of sin, sorrow, and suffering around them, is there so much criticism of them for their efforts to heal the sick and preach the Gospel? The critics of Christian Science might at least endeavour to be consistent.

Because Christian Scientists deny the absolute reality of the existence and power of evil, it no more follows that they deny the relative sense of its reality to the human consciousness, than because the philosophical idealists of to-day deny the actual reality of matter they deny its existence as a phenomenon. For centuries the world has been face to face with the problem of evil, and for centuries the effort has

been persistently made to overcome it whilst admitting its reality. If, however, evil is real it is eternal; if it is eternal, it is hopeless to expect that it can be overcome. Jesus of Nazareth was the man who first showed the world the powerlessness and unreality of evil. Evil, he declared, was a lie, and the only semblance of power a lie can ever even seem to manifest is in the delusion produced by being deceived by it. As soon as the truth is known the temporary power of the lie is destroyed by reason of its very unreality. "Ye shall know the truth," Jesus said, "and the truth shall make you free." Not free, it is certain, from anything that is real, that is from anything God made, but equally certainly free from every lie by reason of its unreality as a lie.

It is scarcely fair to argue that because Christian Scientists have realized the futility of mankind's struggle through the centuries with evil regarded as a reality, and have turned in consequence back to the teaching of Jesus in the effort to meet it as an unreality, that they are ignoring the evidences the material senses given them of sorrow, and suffering, and sickness. "Sickness," Mrs. Eddy has written on p. 460 of *Science and Health*, "is neither imaginary nor unreal—that is, to the frightened, false sense of the patient," and has "therefore to be dealt with through a right apprehension of the truth of being." This right apprehension is surely the knowledge of the truth which makes men free, and the gaining of this knowledge would necessarily bring with it the power to demonstrate its truth—to do, in a word, the works which Jesus declared those who believed on Him would be able to do.

Christian Scientists and those who come to them for help are just as anxious to destroy the evidences of sin and suffering and sickness as those who are most bitterly opposed to the teaching of Christian Science, and most sceptical as to the value of its works. If, therefore, they have turned aside from the old method of fighting evil as a reality, and adopted a method new to-day, though not new altogether, of fighting it as an unreality, it is because they have had evidence which to them is overpowering of the superiority of the new method to the old. This can scarcely be described as burying their heads in the sand, but rather as facing the facts presented to them. Though, if your contributor will forgive me for saying so, the method of ignoring all evidence of Christian Science healing, when it is quite obvious it is going on, is a perilous approach to the reputed habit of the ostrich.

* Mr. Dixon speaks as of "prave 'orts" as Ancient Pistol, according to Fluellen, spoke "at the pridge." If words, as some of the old Greeks believed, could "materialize" into the things they denote, Christian Science would need no defence. There are only one or two points in Mr. Dixon's communication on which we need comment. His concluding statement that we ignore all evidence of Christian Science healing is, as he ought to know, quite inaccurate; we have always said that Christian Science, like many other methods which dispense with ordinary medical treatment, cures a certain number of cases of functional disorder. We take the liberty, however, of explaining these cures in a different way from that taught in *Science and Health*. Mr. Dixon's quotations from that illuminating work prove nothing but the incoherence and ignorance of its author, whoever he or she may have been, in respect not only of science, but of philosophy and logic. Looking into it for ourselves we find in one place the plain statement that "what is called disease does not exist"; in another we are told that "man is never sick"; for the delectable reason that "Mind is not sick and matter cannot be." Again, there is a paragraph headed "All disease is a delusion." But of Mrs. Eddy's self-contradictions there is no end. For instance, immediately after the passage quoted by Mr. Dixon, she condemns most of her own disciples when she says: "If Christian Science is abused by mere smatterers in Science, it becomes a tedious mischief-maker. Instead of scientifically effecting a cure, it starts a petty cross fire over every cripple and invalid, baffling him with the superficial and cold assertion, 'Nothing ails you.'" Thus, out of the prophetess's own mouth is our charge, that Christian Scientists as a body have little sympathy with suffering, justified. Mr. Dixon complains that we criticize the Christian Scientists for their efforts to heal the sick. On this we have only to say that we should be glad that the sick should be healed in any way. What we criticize are what appear to us to be the mischievous consequences of their teaching. If their practice is better than their gospel, that is simply a further proof of the irrational character of the system. *Pace* Mr. Dixon, we agree with our contributor in holding that they do not "face the facts presented to them." That may be why it is so difficult to get properly authenticated facts from them.

HEALING BY ANGER.

DR. H. C. FOLEY writes: As the JOURNAL has lately contained a good deal about the doings of the spiritual quack, I send you the account of how Ulick of the Heads, the first Lord Clairvoyant, was cured of paralysis. I copy the account

from the *History and Antiquities of Kilmacduagh*, mentioning that the scene of the cure is quite near my residence, and that the traditional account is still held by the people. "The circumstances under which Ulick de Burgo received the name Ulick of the Heads are extraordinary. It is difficult to discredit them considering they are found in the pages of a scholar so learned, so conscientious, and so favourably known as the author of *Cambrensis Eboracensis*. Ulick was confined in his castle at Dunkellin for a considerable time by paralysis, which in those days (1542) of active warfare was sure to be attended with serious consequences. Accordingly, his possessions were seized on by neighbours, some of whom were his own kindred. After plundering his extensive territory they attacked his residence, intending to make him prisoner, and seizing all that remained. Bedridden as he was, when it was told that those bound to him by the closest ties of blood had hearts so merciless as to deprive him, a cripple, of the necessities of life, his rage knew no bounds. He forgot his weakness, and cried aloud for 'A horse, a horse!' 'May not,' he added, 'the great God who took away the life of my limb restore it again and enable me to recover my cattle from those merciless thieves.' His attendants, awed by his anger, yielded to his wishes, and placed him with difficulty on horseback. So feeble was he that he was unable to remain in the saddle without assistance. Nothing daunted, he persisted to sit upright, 'till at length the bones emitted a sound loud enough to be heard by his attendants, and in the instant the sinews recovered their strength. His enemies were terror-stricken as he came on the scene; he not only retook his cattle, but brought back in triumph the heads of many of his enemies. Such was the remarkable occurrence that got him popularly known as Ulick of the Heads."

He possibly suffered only from chronic rheumatic arthritis. This disease is to-day not uncommon amongst the people near Dunkellin. The river that flows alongside when the castle mound was probably filled by it possibly made the residence a very damp one.

QUININE IN SYPHILIS.

DR. C. F. MARSHALL (London) writes: Quinine is strongly advocated by Dr. William Murray in the treatment of syphilis in his *Rough Notes on Remedies*. I have also mentioned it as a useful auxiliary indication in my book on *Syphilology*, and have frequently found it of benefit in cases of syphilitic cachexia. But I am not aware of any published cases which were treated exclusively by quinine, nor of any experiments on the action of quinine on the spirochaete.

ASTHMA.

DR. H. G. H. NAYLOR (St. Kilda, Victoria, Australia) writes that he has found the following prescription very useful in asthma: R. Ext. grindel. robust. liq. 5 ii, vin. ipecac. 5 jss, tr. nuc. vom. 5 jss, ammon. carb. gr. 30, pot. iodid. 60, tr. camph. co. 5 ss, spt. chloroform. 5 jss, aqua ad 5 vi. Mft. mist. 5 ss in water three times a day after food. To be taken in water for two or three weeks at a time.

LYNN-THOMAS AND SUTHER FUND.

Twenty-third List of Subscriptions.

MR. WILLIAM SHEEN, M.S., F.R.C.S., 2, St. Andrew's Crescent, Cardiff, Honorary Secretary of this Fund, desires to acknowledge the following subscriptions:

	£	s.	d.
J. D. Williams, Cardiff	1 0
S. J. C. Fraser, Hastings	1 0
W. C. Griffiths, Pontardulais	2 0

EPSOM AND LETTSOM.

A CORRESPONDENT sends the following from the diary of a young lady whose family were patients of Dr. Lettsom. It recently appeared in *Notes and Queries*:

Next day it was enough to vex one;
There came a bill from Dr. Lettsom.
The bill was due that very day,
And Pa had not enough to pay,
For what was saved to pay poor Lettsom
Was spent the day before at Epsom.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	0 4 0
Each additional line	0 1 6
A whole column	2 13 4
A page	8 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

S.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

An Address

ON

THE MODERN TREATMENT OF
FRACTURES.DELIVERED AT THE ANNUAL MEETING OF THE CARDIFF
MEDICAL SOCIETY ON JUNE 4TH.

By JUST LUCAS-CHAMPIONNIERE.

HONORARY SURGEON TO THE HÔTEL-DIEU, PARIS; MEMBER OF THE
FRENCH ACADEMIE DE MEDECINE; PRESIDENT OF THE
INTERNATIONAL SOCIETY OF SURGERY.

GENTLEMEN,—I no doubt owe the honour you have done me in asking me to deliver an address on this occasion to the fact that I am an old student of the British universities. When I was a young man, soon after completing my studies in Paris I paid a visit to this island, early enough to see the surgical science of Lister at its dawn, and I am happy to-day to remember and to state that since that time I have been among those who have always rendered just homage to the science of your country. This is not because, like certain philosophers, I think that Science has no country; on the contrary, I believe that we ought to be as proud of our country's men of science as of our great soldiers. But the man of science is fortunate in that he is imbued with an additional sentiment added to the love of his own country, and that is a sincere admiration and brotherly sympathy for all those who in foreign countries have enriched the science to which he himself has devoted his life.

The best way of proving sympathy and sincere admiration for a scientific association which meets to celebrate a long and laborious past is to present to it a review of a subject to which the speaker has for many years himself given much attention. I propose, therefore, on this occasion to speak on the modern treatment of fractures, not only because I believe firmly in the efficacy of a mode of treatment which I myself introduced, but also because the profession in this country is still under the influence of the righteous emotion caused in the surgical world by the unjust accusation to which your compatriots were subjected.

That it is possible for such injustices to occur is due not merely to the existence of a feeling unfriendly to the medical profession, but also to the important changes which the method of treating fractures has recently undergone, changes not fully known to the medical world, and still more imperfectly known to the non-medical public. The importance and gravity of the subject will, I hope, interest you sufficiently to induce you to forgive any deficiencies in my address.

TREATMENT BY REDUCTION AND SPLINTS.

The truth is that within recent times the classical treatment of fractures has been undergoing a radical change.

It is a remarkable fact that the treatment of fractures, the beginnings of which go back so far into the mists of time that we have no idea of the era when splints and treatment by immobilization were invented, has always rested upon the same data and upon the same principles ever since the first beginnings of the science of surgery.

Read any treatise on fractures, from the most ancient to the most modern, from Hippocrates to Ambroise Paré, to Dupuytren and Malgaigne and Hamilton; read all the encyclopædias, even the titles of which I cannot enumerate—every one of them will tell you that movement is the enemy of the formation of callus, and of bony repair; that it is an obstacle to the formation of callus, so that defective consolidation, whenever it is observed, is attributed to movement having been permitted. In order to obtain the union of fractures, all practitioners have taken account of one fact alone, that a bone is a rigid lever. When it is broken the fragments must be fixed in the position of the normal bone and immobilized. To reduce and to immobilize are the only measures upon which attention is riveted.

Ambroise Paré, the first surgeon who boldly relied on his own personal observation, whose imagination was always alive to find out something new, often hesitates

between his own imagination and the ancient traditions as to fractures; but he ends up always with remarks which impel him to greater exactness and greater violence to ensure the reduction of fractures and their maintenance in position. Beyond this he gives information only as to the drugs which might favour the production and the union of bone. With the exception of this last point, the aims of Dupuytren, of Malgaigne, and of Hamilton are exactly the same, although, like all nineteenth century writers, being convinced that they possess much more accurate views on anatomy and physics than the older writers, they apply procedures for reduction and maintenance still more rigorously, and invent new details in the methods of reduction and in splints.

The strange thing is that they are so persuaded that they really reduce fractures, and that they favour union by immobilization, that they pay little or no heed to clinical observation. It does not occur to them to try any other means. If their results are bad, their only thought is to attribute the failure to the inadequacy of the means of reduction and immobilization which they had adopted.

Here and there in their writings on fractures it can be clearly perceived that some great observers were disturbed by facts which as it were struck them in spite of themselves. Malgaigne had indeed seen untoward results due to muscular contraction in fractures of the lower limb, and he thought that in the inclined plane he had found a means of preventing them. Hamilton, speaking of fractures of the elbow, recommends that the fragments should be immediately mobilized at the risk of not obtaining good adjustment, because it is essential to prevent ankylosis. Velpéau recommended that in fracture of the radius the splints should never be tightly applied, for fear of causing permanent ankylosis. The doubts expressed by these surgeons show that the evil consequences of immobilization could not have been altogether unknown to them, yet not one of them was bold enough to run counter to accepted opinions; all soon returned to the employment of the most complete possible immobilization after the most violent reduction. We find the greatest surgeons devising most extravagant appliances, such as Dupuytren's splints for fracture of the radius, the action of which is utterly futile, because, from a *point d'appui* in itself detestable, it has to oppose the contraction of the muscles, and the cicatricial contraction at the site of the fracture; or again, that apparatus of Desault for fracture of the clavicle, which recalls the "Maiden," the torture jacket of the Middle Ages, under which the contraction of the muscles renders certain in the future the maximum possible deformity owing to overriding of the fragments of the bone.

Every one of these authors, not excluding even those who hesitated, all come back to the formula which Malgaigne very frankly placed at the head of his great treatise on fractures: *Immobilisation est la base.*

"The treatment of fractures can be summed up in two great indications: Reduce the fracture and keep it reduced until consolidation is complete."

The nineteenth century saw the birth of a considerable number of works on fractures; all of them rely, above everything else, on physical or geometrical theories of the mechanism of fractures; if they discuss treatment at all, it is only to describe new means for the forcible reduction of fractures and their maintenance in position.

TREATMENT BY IRREMOVABLE APPLIANCES.

An enormous part in treatment of this kind has been played by a new invention—that of irremovable apparatus. This method of treatment is extremely valuable in certain cases, but the infatuation for these appliances has been such that in a very large number of cases they are the cause of the very worst evils that can be produced by immobilization. To realize the regrettable results of this absolute immobilization upon the nutrition of the limbs we must come down to our own times. The problem presented by the treatment of fractures, which used to be "reduce, and maintain relative immobility," has now become "reduce, and enforce absolute immobility of one or several segments of the limb without regard to the duration of the immobilization."

THE ORIGIN OF MODERN TREATMENT.

It was perhaps the very exaggeration of the evil produced by the abuse of this ingenious invention that

contributed to bring about an understanding of the necessity for a change in treatment. So far as I myself am concerned, it was the excess of the evil which, more than any other fact, particularly struck me. The excess of the evil opened my eyes to the inconveniences of immobility, and to the part which mobility ought to play in the repair of fractures. This observation it was which emboldened me to make mobilization a leading principle in the treatment of fractures. The success of the treatment has been due to the very numerous clinical observations which have demonstrated the truth of the principle.

But to bring about an abrupt change in treatment, and to replace a bad by a good line of treatment, it is not alone sufficient for observers to recognize the existence of the evil. Our art must advance by slow steps, and it is well to learn how a change which upsets all the oldest principles could be made, how it could even enter the mind of an observer, and how it could be adopted by the majority of surgeons accustomed to another practice, which, although it presents many disadvantages, yet has for centuries rendered services at once incontestable and uncontested. This progress in therapeutics must be brought into relation with the great scientific changes by which modern surgery has been created. The paradoxical idea of introducing movement as a part of the treatment of fractures, and its acceptance by the medical public, must in fact have owed its development and its success to some very strong reasons.

Before making known the results of my own observations and experience, I long meditated upon the facts, and I can assert that I only made up my mind to publish conclusions contrary to all received ideas, and to initiate a revolution in treatment, because I was witnessing and taking a part in the transformation which surgery was undergoing.

Pasteur and Lister had so completely upset all our earlier notions that their example forbade any hesitation in submitting the best established scientific and practical theories to severe criticism. They inspired me with the courage which alone could lead to useful discoveries, and transform what it is most difficult to transform—practices resting upon most ancient customs, such as are to be described by the word "routine."

My assertions as to the remote consequences of the discoveries of Lister may be considered exaggerated, yet I am profoundly convinced of this indirect influence of a great piece of scientific work, and more especially of a piece of work which brought about a radical transformation not only in scientific theory, but also in the mechanical execution of the details of the surgeon's own acts, a change which completely upset his habits in practice.

This extraordinary piece of work which upset all our habits and destroyed the whole edifice of our surgical education, produced in us such an aptitude for change that I also found it possible to accomplish another piece of destructive scientific work, which, while it has its own dangers, can alone lead to great transformations in science and in practice.

The relation of the change which I have advocated to our older education is in fact very singular. A distinguished American surgeon, Caldwell, of Freeport, who had assiduously followed my practice at the Beagion Hospital, and had watched my treatment in the various types of fractures treated there, said in summing the matter up: "It is a very strange thing, after spending all one's life as a surgeon and following scrupulously the precepts of surgery, to realize that one has been steadily deceived, and that in a practical matter so well established as the treatment of fractures one has been doing evil where one believed that one was doing good."

Is not this the very same idea that Sir William Bennett has sought to express in the introduction to his *Lectures on the use of Massage and Early Passive Movements in Recent Fractures*?

Indeed, it cannot but excite surprise in the mind of an intelligent person that the stiffness, pain, and other disadvantages which so constantly follow the treatment of fractures upon classical lines, should have been countenanced for so many years when they can, in the majority of cases, be entirely obviated by a treatment so simple as that described in the following lectures.

To break so completely with acquired habits, even when the change is the consequence of numerous positive obser-

vations, is in truth a revolution, and revolutions are only made when the reasons in their favour are many and strong. The transformation wrought in our scientific mentality, giving it a degree of boldness which might seem to be temerity, undoubtedly had a leading part in influencing my course.

But the advance of surgery is always complex, and it must not be forgotten that other considerations influenced my mind, leading me to study the fundamental influence of movement on the vitality and on the regeneration of organs damaged or destroyed by injury. It is no doubt true that these considerations also have no very direct bearing, but they are the consequence of the advance of science and of the contemporary progress of medicine and physiology. When the study of many of the empirical methods of massage and gymnastics was commenced in France, the study of movement was at the same time founded and developed. In this study two great French men of science were the chief leaders. Marey, by his methodical and in a certain sense mathematical study of all movements, taught us to register and reproduce them in pictures which were at once true and expressive; while Lagrange introduced medical analysis into the study of functional and gymnastic movements by applying the physical ideas of Marey to sport and training. It is, at any rate, the fact that my acquaintance with these two men of science contributed to lead me to study movement from the point of view of its physiological and pathological consequences in fractures and in injuries of the joints.

Since that time a considerable number of men of science, teachers of gymnastics, masseurs, and others, have carefully studied all the scientific facts bearing on the subject, and the present position of what is called physio-therapy is the result of a series of quite modern investigations.

The study of movements from the educational and therapeutic points of view seems to have originated in France during the last century. The aims of the gymnastic methods of Amoros and Laisné were at first educational, but their applications in my country long remained very restricted, whereas in England and in America the love of sport gave origin to important empirical ideas with regard to movement and to training. It was, however, in Sweden and Norway especially that the study of movement from the educational point of view and the development of the art of massage were given a truly scientific character, and was controlled by men of science and doctors, while in every other country it remained the property of empirics.

We must, in fact, not fail to recognize that the share of Sweden and Norway in the evolution of massage and gymnastics has been scientific. It must not be supposed that the fundamental difference between the system of gymnastics known as Swedish and other systems lies in any actual difference in the movements. The merit of the Swedish system of gymnastics lies in the application of scientific rules and of a definite method. The cause of its success is to be found in this methodization. Various very different forms of movement are capable of giving equally successful results if they are measured and if they are performed on a regulated system. Again, it is the method or system which has rendered it possible to use this therapeutic procedure in many very different forms of education and treatment.

TREATMENT BY MASSAGE AND EARLY MOVEMENT.

With regard to the treatment of fractures which I advocate, I will say this, that my success has been due, more than anything else, to the introduction of a strict method of applying special forms of movement to the treatment of fractures. It is the method which has rendered possible the generalization of this therapeutic measure and its application to all forms of injury of the skeleton and of the articulations.

It is not unprofitable thus to recall the spirit of the method which served as a clue to guide me in working out a therapeutic revolution, and it is in fact true that each successive step can be traced in the history of my various trials and investigations, and in the order in which my various applications of the method succeeded one another. I began by lessening the degree of immobility; next I did away with it altogether; next I began to use movements at an early stage; then I began to use them immediately after the injury; finally, I made use of massage, that is to

say, of a method of mobilizing the muscles, the joints, and even the bony fragments. It was necessary to define the indications and the limits of this special form of movement. Thus it was that years of observation and experiment led me to establish the bold practice of methodical therapeutic mobilization.

It is a singular thing to realize that it was through my own detailed studies that I did this, and that, apart from my personal researches, nothing was published before the appearance of the description of my method. The only instance in which massage had been used for a fracture at about the time at which I developed a complete method was for fracture of the patella; it was so used by Metzger, who apologized for applying massage to a fracture, on the ground, as he said, that in this particular fracture bony union could not be obtained. The same masseur, in discussing sprains of the ankle, stated specifically that massage should not be used if the malleolus was fractured.

At the very same period I showed, in opposition to this, that massage favoured the production of new bone, and later on the beautiful experiments of Cornil on animals proved that this result of the mobilization of the fragments was invariably to be observed, and in young animals was too great.

Having carefully studied all earlier observations which might have served as precedents for my method of mobilization and massage, I have satisfied myself that none such existed.

SUTURE OF BONES.

Since my method was devised and generalized two important means for the study and the treatment of fractures have seen the light of day; these are suture of bones and radiography.

I do not wish to decry immediate suture of fractured bones. When Sir Hector Cameron performed the first suture of the patella, when Lord Lister published his articles on the subject, I was the first to follow their example. I believe, indeed, that I am to this day the surgeon who has performed the operation of suture of the patella in a greater number of cases than any other in the world. I believe also that there are few surgeons more familiar than I with the suture of bones in general. I consider that most valuable results can be obtained from immediate suture performed antiseptically.

But the question is, Does the suture of bones used as a general method for treating fractures in the way recommended by Arbuthnot Lane in England, Lambotte of Antwerp, Tuffier of Paris, and many other surgeons, deserve to be generalized and preferred to every other method? Without denying its conspicuous advantages, I must say that for my part I do not think so. I believe that it is a sort of continuation of the old method of reduction and fixation of the fragments. It would seem, indeed, to be the ideal of reduction followed by immobilization, and has in fact been held to be the most perfect realization of the old precept as to the treatment of fractures. It is certain also that the more the method of mobilization is developed the fewer will be the occasions on which immediate suture will be performed. If, as I have shown, a small amount of movement assists the process of repair at the site of fracture, it is quite evident that suture cannot be the ideal mode of treatment, for it ought, if properly performed, to do away with all movement of the fragments. I can at once give a practical example of this; suture of the olecranon is undoubtedly the simplest of all operations of the kind. I have done it for old fractures inadequately treated by other surgeons. I have never had occasion to do it for recent fractures properly treated by my method, because perfect recovery is obtained within a fortnight without operation.

RADIOGRAPHY.

Since I began the treatment of fractures by movement, light has been thrown on the study and the treatment of fractures from another new and important source; this is the application of radiography to the examination and to the treatment of fractures.

Although I am the author of an essay on the errors of radiography, I appreciate the importance of radiography in regard to fractures; but I hold that on the one hand radiography cannot dispense us from the study of the symptoms of fractures, and on the other that it

cannot warrant an untrained person replacing a doctor in making a diagnosis and in treating fractures.

Radiography gives us only a picture of the projection of a bone, and is subject, therefore, to many more drawbacks than ordinary photography by reflection. Consequently it is necessary very critically to examine images which for a multitude of reasons may give misleading pictures of the site of the fracture. It is necessary to learn how to appreciate the real value of a radiogram; only after much experience can one become a good judge of radiograms of fractures, even when these radiograms have been well taken. A radiogram which is badly taken may give rise to a multitude of errors of representation which ought to be known, and which produce many mistaken ideas in the mind of the non-medical public.

Subject to these two reservations, radiography is a marvellous aid in the diagnosis and in the treatment of fractures. From this time forth the surgeon ought never to fail to use it whenever it is possible to do so. Nevertheless the value of the help it can give varies very much. In the immense majority of cases there is very little chance that abstention from resort to radiography will prevent us from arriving at a correct diagnosis and the institution of proper treatment; it is essentially necessary in rare cases only. In the majority of instances it is only an additional security, giving a useful assurance to us, and to the friends of the injured person an interesting demonstration, and a document for future use.

Radiography has afforded me very special help in all that concerns my own standpoint with regard to the treatment of fractures. I have long maintained that surgeons who supposed that in reducing fractures they adjusted the bony fragments end to end and restored them to their normal position were deceiving themselves, and that in spite of faulty position, in spite of a certain degree of persistent overriding, the function of the limb again became perfect. The object which we must have in view in treatment, then, must not be this ideal juxtaposition.

Radiography has, in fact, surprised surgeons very much by showing them fractures well and soundly cured, with excellent functional results, but with considerable bony displacement. Very often, indeed, surgeons not fully acquainted with these matters, and still more patients, on examining such radiograms have been led to believe that errors have been made, even when the function of the limb is as perfect as the nature of the injury renders possible. What we are thus taught will prove very valuable in establishing a modern treatment of fractures.

THE MODERN METHOD.

After this very short summary of the history of the treatment of fractures down to the present day, let me next explain my conception of what this treatment by movement is, and state the new facts observed by me which give a revolutionary character to my method.

A certain amount of movement between the fragments ensures the best bony repair; this is the corner-stone on which my method is based. Every movement which is not injurious by reason of its amplitude favours repair; but it must be understood that the movement must be measured—dosed, so to say.

The movement which is necessary for the repair of the bones is not less necessary to the vitality of all the constituent parts of the limb, and particularly for all the organs of motion—joints, muscles, ligaments, and tendons.

The relation which the movements have to pain experienced by the patient are not such as is commonly believed; certain kinds of movement help to relieve the pain. Immobilization, which seems to relieve, only gives momentary relief, for it prepares the way for other pains in the future. Mobilization, gently performed as early as possible after the injury to the bones, is the method which best promotes disappearance of the pain.

Massage affords the best form of movement. By simple mobilization, by massage, and even by his own examination, the surgeon ought never to cause pain, for the pain so caused leads to fresh pain and produces complications.

The reduction of a fracture is only a relative necessity; it should be resorted to only in certain deformations of the axis of the bone which are incompatible with the function of the limb—lower third of the leg, shaft of the humerus. In a large number of cases the manoeuvre of reduction is useless; it is useless in all fractures of the radius with

impaction and moderate deformity, in most fractures of the upper extremity of the humerus, and in the great majority of fractures of the neck of the femur. In all fractures in which the displacement is due to muscular contraction any attempt at reduction is useless, as in fracture of the clavicle, of the olecranon, and many fractures of the malleoli. After massage the fracture is either spontaneously reduced, as in the case of the olecranon, or is very easy to maintain reduced, as in the case of the clavicle and malleolus. Those conditions which favour the vitality of the limb are all more important than those which produce immobilization of the fragments. The fact that shortening has not the injurious influence on repair which it is said to have should not be lost sight of when considering displacement. A moderate degree of shortening which does not change the static position of a limb is favourable to repair. The muscles surrounding a shortened lever act more rapidly and better than upon a lever on which they are stretched. A certain amount of shortening ought not to be interfered with, as it is favourable to the repair of a broken bone.

Massage has so great an effect in stimulating bony secretion at the site of fracture that in children, in whom the activity of the production of bone is great, massage ought not to be applied, save with great moderation, for fear of provoking excessive osseous secretion—in fact, a tumour. In their case simple mobilization is often sufficient.

Mobilization from the beginning, within the first twenty-four or forty-eight hours, is of capital importance, and at this stage movements of very small amplitude are sufficient; passive or induced movements are the best at the beginning. Active or spontaneous movements ought to be measured and directed by the surgeon; to allow the patient to follow his own fancy with regard to active movements is dangerous—all the more dangerous because with my method the pain caused by movement disappears from the beginning, and therefore does not limit the untimely action of voluntary movement. The pain experienced and the degree of sensitiveness of the callus are the best guides in directing and in permitting movement by the patient.

The secondary treatment of fractures and their supervision ought to be prolonged. Functional use of a fractured limb is the condition most favourable to its regaining active power. Even during this secondary period everything likely to irritate the region of the callus ought to be avoided. It is useless to cause pain by movements exaggerated in amplitude or by resort to forcible manipulation.

While before my investigations the surgeon contented himself, after having reduced a fracture, by awaiting cure, the modern surgeon should play a much more active, much more personal, and much less simple part. He ought not only to diagnose the fracture but ought to make its exact nature visible by a radiographic picture, and then take action to obtain not only solidity of the limb, but also to restore its suppleness, its regularity of action, and its power. He must not merely await the solidification of the skeleton. Moreover, his treatment must vary a great deal according to

1. The age, sex, and constitution of the patient.
2. The variety in the site of the fracture,
3. The kind of fracture of the limb,
4. The general or local health of the patient,
5. His occupation.

and according also to the circumstances under which he is called upon to act, for if he cannot ensure proper personal supervision of mobilization, massage, and the supervision of the movements, it may happen that he will be compelled to replace an excellent method of mobilization by a moderately good method of suture, or absolute immobilization.

The surgeon needs a great deal of experience to conduct the treatment of a fracture in the best way, and I cannot help asking with some anxiety how a non-medical tribunal is to form a judgement on questions so complex, should the patient and his medical attendants cease to be in accord.

The situation is complicated. Well-to-do people bring actions against surgeons because they continue to experience pain or stiffness after a fracture; workmen

reproach the surgeon because he cures them too well, inasmuch as by causing the disappearance of all secondary pain, accidents are not followed by the permanent infirmity for which they hoped.

The whole history of the surgery of fractures cannot be related in an address which is already too long, but I shall have succeeded in my purpose if I have made plain to you to how great an extent the duty of the surgeon has become, difficult indeed, but effective in this matter of fractures. Instead of waiting for the injured person to cure himself, we can cure him and quickly restore to him the use of his limb.

It is a laborious task, more difficult than the banal application of irremovable appliances; it is still insufficiently understood by the profession, and altogether unknown to the public. But I am proud to think that in your country it has met so favourable a reception that you have been willing to listen to the exposition of the subject which I have to-day offered to you as a tribute of fraternal homage.

An Address

ON THE

PRODRAMAS OF MIGRAINE.

DELIVERED BEFORE THE WESTMINSTER DIVISION OF THE
BRITISH MEDICAL ASSOCIATION.

BY

SIR WILLIAM R. GOWERS, M.D. LOND., F.R.S.

GENTLEMEN,—I have chosen a subject for your consideration with which every practitioner is familiar from the accounts of his patients, and a good many are also well acquainted from personal suffering—the curious sensory symptoms that constitute the premonition of attacks of migraine, using the term as equivalent to paroxysmal headache. The symptoms occur before every form of such headaches, those which are bilateral, as well as those that may be strictly termed “hemispheric,” but both are common without premonition.

The knowledge we have of these peculiar symptoms, the prodromas of migraine, is very small, compared with their frequency, their detailed features, and the facility which frequent recurrence affords for their collection. It is easy to explain the paucity of facts. Observation under conditions of distress is not easy, especially when minute precision is needed. A graphic presentation of visual sensations, such as that which was afforded by Dr. Airey, can only be recorded from memory, because vision is too much interfered with by the subjective disturbance at the time. A knowledge of, or at least some acquaintance with, the physiology of sensation is necessary for the full use of the opportunities which are met with, especially by personal observation. It is the hope that I may excite some to careful record, that makes me choose this subject for consideration, and describe some cases which illustrate the leading features of these strange manifestations. I will, however, endeavour to avoid repeating those that I have given in the Bowman Lecture on Subjective Sensations of Sound, and in the lecture on migraine in *The Borderland of Epilepsy*. I do not propose to discuss their nature, although it is difficult to avoid alluding to the hypotheses that have been brought forward.

The prodromas are a functional disturbance in the sensory region, and so is the headache which succeeds. But the headache may be termed a coarse disturbance consisting of pain, often most intense, and sometimes with some secondary effects of its severity. On the other hand, it may be slight and of short duration, and it may be even absent, the prodroma occurring alone. These premonitory symptoms, although sensory, do not include pain. They are restricted in range. The sense of sight is often involved, sometimes by loss, partial or general, sometimes by an elaborate display of its higher crude functions in light, colour and apparent motion. Other special senses do not participate, except the sense of touch. Neither smell, taste, nor hearing seems to be involved, although there is rarely a slight degree of vertigo, the precise nature of which is not clear. The involvement of cutaneous sensibility seems to be of touch, and is a frequent and

marked manifestation. The arm is its most common seat. It may be felt in the tips of the fingers, passing along them, and going no further, or as a zone of tingling around the wrist, which slowly ascends the arm, in the course of ten to fifteen minutes. As it passes up, it leaves behind it lessened sensibility, which gradually becomes normal, and with this some degree of loss of power, apparently the result of inhibition. After reaching the shoulder, the tingling hardly ever descends the trunk to the leg, although it may in rare cases be felt in the foot, and sometimes ascends the leg. Often, after ascending the arm, or primarily, it is felt at the mouth, in the lips, sometimes in the gums and tongue, on one side, but in the lips it is often felt on both sides. Here it is an intense tingling, sometimes compared to pins and needles, apparently as slight pricking, but it is never described as pain. It seems here also to leave distinct diminution of sensibility behind it, but on this we much need further observations, on the degree and duration and character of impairment.

Still more frequently the premonition consists in interference with sight. There may be impairment of one half of the field of vision, seldom, if ever, so complete as it is from organic disease, not reaching actually the middle line. Often the loss on one side is associated with a luminous spectrum, of which a typical form is that figured by Dr. Airey in the *Philosophical Transactions*. This begins as a star, a little to one side of the fixing point, which enlarges, becoming first an angled sphere and then a serrated or zigzag outline which breaks below, and the elements of which it consists become progressively smaller towards the free extremity. They are often coloured, adjacent ones differing. Sometimes they are luminous without colour. Often they are double. Within the zigzag, as it expands, there is a misty luminosity which becomes fainter internally, and hinders sight if an object is looked at. Thus the dimness of vision within the bright or coloured zigzag outline resembles the numbness left by the tingling as it passes up the arm. After its expansion, the spectrum often ends by a whirling explosive appearance. In other cases an angled light appears near one lateral edge of the field, or both, sometimes several interlacing zigzags. Or a stellate bright object may appear on one side and remain without expanding. In other cases a sort of luminous lacework occupies the middle of the field, sometimes bounded by a brighter band. Various other spectra are seen, of which we much need precise drawings.

This sensory disturbance may be always the same in some patients, in others varying. The premonition is often unilateral in character, and the succeeding headache is felt on the opposite side of the head. Sometimes the premonition is felt on both sides or has no lateral significance, and then it is succeeded by a medial or bilateral headache. These constitute the common rule, but exceptions are frequent; at least, a patient may fail to recognize a one-sided seat of the headache which succeeds a unilateral prodroma. The headache may be successively bilateral, that on one side ceasing when pain develops on the other side. Moreover, the premonition when unilateral may pass beyond the middle line in its course, although the headache is confined to one side.

One other frequent symptom of the warning remains to be mentioned. When the sensory disturbance is right-sided it is often accompanied by impairment of speech of the character of aphasia. Sometimes the loss is almost complete; in other cases there is only a difficulty in the use of words. But we need much to know more precise details of this loss when it occurs.

Of the process which induces the premonition we have only hypothesis to rest on. There is clearly a disturbance of function in certain parts of the cerebral hemisphere, probably the cortex, which is the subsequent seat of the pain. The disturbance of function is apparently crude, and seems, as it were, to ripple through the centre, leaving an inhibited condition which quickly passes away.

Any hypothesis presents difficulties. That which is least difficult is the opinion that local vasomotor spasm causes anaemia in a certain region, and that subsequent dilatation of the arteries is the cause of the subsequent pain. There is often superficial pallor and coldness during both the sensory premonition and the early part of the headache, but it is not always con-

spicuous, and the state of the surface is only evidence of the occurrence of vasomotor derangement, and not of its kind. A greater difficulty is constituted by the uniform character of the nervous symptoms in most cases, and the difficulty in assuming that such a nervous discharge can be explained by such a process as vasomotor spasm. But the production of an effect may be facilitated by repetition. Some time after a previous headache an attack may be brought on by over-fatigue or by error in diet, which would have no effect soon after one. This has given rise to the assumption that some toxic state is developed in the system. It is, I think, certain that the sufferers often have a pronounced gouty inheritance. But the assumption of a peculiar blood state throws no light on the immediate mechanism of the attacks, and is quite compatible with the theory of vasomotor disturbance. Certainly marked benefit is often obtained from the regular administration of nitroglycerine (with strychnine), which seems to act by steadying the vasomotor nerves and rendering them less prone to derangement. I have never had an opportunity of observing the retinal vessels during a sensory prodroma, but during the headache I have seen no abnormality in size, and the known symptoms during vasomotor spasm of the retinal artery bear no resemblance to those which precede migraine.

The time of life at which migraine begins varies much. Often the headaches are said to go back to the period of earliest memory: they may begin only when adult age is reached, or a prodroma is added to those which before occurred without one. They may commence at any later period, and often as late as fifty or after. At any adult age, the prodroma may occur alone, at least sometimes, the headache being or becoming slight and trifling. When a visual spectrum has often preceded the headache, it is sometimes called into separate existence without succeeding headache by any flickering light before the eyes, such as a reflection from rippling water. A surgeon, who had suffered from migraine for many years, sometimes set up his customary spectrum by the reflection from the knife with which he was operating. Thus the functional disturbance is apparently the same as is produced by actual vision.

In middle or later life the occurrence of an unaccounted premonition may give rise to much concern, especially if it involves the arm, lips, or speech. It may seem like a vascular lesion in the brain, especially if it occurs without succeeding headache, or if this is only slight. Even a more severe degree of pain in the opposite side of the brain may seem the effect of a presumed cerebral lesion, to the medical practitioner as well as to the patient, who is likely to consult his adviser in alarm on account of symptoms which are new in his experience. I have known this to occur, and an erroneous diagnosis to be made without any other foundation. The symptoms which alarm the patient closely correspond to the premigrainous premonition in detailed character, and this should therefore be familiar, for the correspondence may always be trusted. I will indicate the points on which reliance may be placed in describing some cases to illustrate the general facts I have mentioned, as I now propose to do. Especial weight may be placed on the deliberate progress of the symptoms, such as the sensation of numbness ascending the arm, and on the definite numbness in the lips and its extension to both sides of the lips, and on the brief defect of sensation which follows it, and on the affection of vision, and the definite but transient interference with speech. This is always associated with right-sided symptoms in vision or the arm or face. The constant vanishing of the symptoms in the order in which they come on is also of great significance.

A young man of 17 had suffered from migraine since 12, the intervals ranging from a week to several months. Coloured zigzags appear on the right side of the field, and he cannot see on the right side. The spectrum expands and passes to the left, together with the impairment, which thus involves at last the whole field. After it has passed away, speech is almost lost; for half an hour he is only able to utter a single word of four or five he wants to say. When this ceases the headache begins at the back of the left eye, passing to the left side of the head, for six hours or so, it persists throughout behind the eye. There was no sickness, but great general sense of cold, and a very small pulse.

A man of 37, who had had rheumatic fever in early life, had suffered from left-sided headaches for a year, about once a month. They began sometimes soon after waking in the morning, more often at any time in the day. First there is

numbness in the tips of the fingers of the right hand, which passes slowly up the arm and then is felt in the right side of the cheek and mouth, but does not go to the throat. He is then unable to utter words correctly; there is not difficulty in getting the right word, but a difficulty in uttering it, apparently in articulation. Then this and the numbness cease, and headache comes on in the left frontal region, or left side of the occiput. On nitroglycerine the attacks ceased for nearly a year, and they returned less frequently and in very slight degree, but with the same premonition, and he had occasionally, during sleep, a right-sided convulsion, apparently of idiopathic epilepsy. There was no optic neuritis or sign of organic disease.

A member of our own profession, aged 37, whose mother also suffered from migraine, had had attacks as long as he could remember. The headaches had been preceded by visual symptoms, which occurred alone once or twice a week when he was seen, without succeeding headache. The condition begins as a luminous zigzag near the periphery on one side; it becomes larger, without colour, and inside it is a yellowish luminosity. Then it seems to him to cross to the other side, but there is no definite hemianopia. The side varies on which it appears, but the headache he had previously was always on the side opposite to that on which the spectrum began, and was accompanied by a small spot of hyperaesthesia on the occipital scalp. Formerly, when the premonition was on the right side and the headache on the left, aphasia formed part of it, and the first symptom was numbness in the hand, beginning in the hypotenar region and passing along the tips of the fingers to the thumb, which passed off in the same order, and never ascended the arm.

When a prodroma in the arm is associated with disturbance of vision the former usually occurs first. But it occurred last in one patient:

A lad of 18 suffered from headaches, which came on at intervals of six weeks or longer, sometimes six months, and then two or three headaches occurred at much shorter intervals. First there is an appearance of zigzag shaped objects before the eyes, not coloured, extending over the fields, but intermittently, and anything at which he is looking disappears and then can be seen again to vanish. This is repeated several times, and is followed by slight dimness of vision to one side. Then numbness occurs in one hand or the other, sometimes in the shoulder, and then it passes down the side and the leg. Sometimes it passes up to the face and involves the tongue and throat, like pins and needles, on one side only, but the side varies in different attacks. It is slow in progress, taking half an hour to go through the side, and seems to recede in waves in 1½ courses, as did the affection of sight. Sensation in the skin seems dimmed by it, but is not lost. When it is over headache comes on, severe, usually on the side of the head opposite to that on which the prodroma was felt, rarely on the same side, lasting from one to several hours, and attended by vomiting. I could not learn the character of the premonition of the same-sided headache.

In almost every case which is carefully studied the prodroma presents some special peculiarity, and a number of precise records must be collected and compared, to furnish the ground for any inference regarding their features. Momentary symptoms are usually characteristic of the warning of epilepsy, but in one case of migraine the prodroma was a bright spot of light, with a blue margin, which lasted only for a moment, but returned three or four times in the course of an hour, when severe pain came on, on one side of the head. The patient was a woman, 35 years of age, who had suffered thus for many years. Her mother also had migraine.

I have said that in bilateral or medial headaches, if there is a prodroma, it is of similar distribution. Thus a man, whose attacks of pain were severe and were situated in the middle line of the head, experienced a premonition which consisted in a concentric contraction of the field of vision, which became restricted to a small spot in the middle of the normal field. Before this he sometimes had tingling in both hands. In another case there is first general dimness of sight and after it has lasted a quarter of an hour, bright luminous spots appear at each outer side of the conjoined field of vision, and are seen in rapid movement. They do not extend far into the field, and one or two are larger than the others. When they disappear, headache comes on across the forehead and behind both eyes. It lasts only an hour, but he feels tired for the rest of the day.

Migraine and epilepsy occasionally coexist in the same patient, as in the second case mentioned above; but generally whichever disease existed first presents a diminution after the second has developed. That this is the rule cannot be doubted if a large number of cases are compared. I pointed this out in the *Borderland of Epilepsy*, and mentioned some examples. The two

affections seem, however, essentially independent. I have only once or twice met with a true connexion between them, the visual premonition of migraine becoming quickened into the aura of the epileptic fits. But such a relation is extremely rare. As a rule, the prodroma is always most deliberate, and is never attended by motor spasm, or, indeed, any motor symptoms, except the slight weakness when the numbness has just passed. Very rarely some spasm may be met with in association with the subsequent headache, when it is very intense. In a clergyman of 47, whose headaches began at 20, the early symptoms were unusual, inasmuch as right hemianopic dimness of sight, for a quarter of an hour, was followed by right-sided headache, chiefly at a spot in the right side of the occiput. The pain also passed down the spine to both legs and caused a twitching backwards, apparently semi-convulsive. The pain reached its height in six hours. There was no change in consciousness. The motor spasm was clearly a secondary effect of the pain. It had given rise to the diagnosis of epilepsy, and also of hysterio-epilepsy, to neither of which it had any relation.

In another case, a woman with very severe headaches of long duration—two days—which were attended during their height by semiconsciousness, and sometimes by spasm on the left side when the headache had reached its intensity, on one occasion the spasm made her fall out of bed. The prodroma was also long, lasting two hours, and consisted of coloured zigzags, which sometimes occurred alone.

That which is presented to the patient in the sensory premonition is a release of function, the form of which is thereby shown, and also its character. It is this which gives importance to the precise details. Most of the unilateral premonitions may be explained by the limitation of the disturbance to one hemisphere, by whatever it is excited, arterial spasm or whatever may be productive of the activity of function. But in rare cases the visual loss has the form of transverse hemianopia, loss of the upper or lower half of the combined field. In the hinder part of each hemisphere is represented the lateral half of the field, as a combination of the upper and lower quadrants. But the transverse loss implies an affection of the two upper or two lower lateral quadrants, situated in different hemispheres. This may be effected by arterial spasm involving symmetrical branches in the two hemispheres, on the supposition that arterial spasm excites the initial disturbance; or it is conceivable that this spasm may be on one side only, and the functional inhibition induced may act secondarily on the related centre in the other hemisphere.

I have elsewhere mentioned some examples of transverse hemianopia, loss of the upper half. It was also described by a woman, aged 38, as a prodroma of headaches from which she had suffered for twenty years. The first symptom was loss of the lower half of the combined field, observed with each eye. Often, but not always, luminous zigzags were seen in the dim region, bright but without colour. During recent years this had been followed by other symptoms, numbness and tingling in the upper lip or in one thumb, and on one occasion a patch was felt on the back of the left foot. Sometimes it was felt on the right side of the nose and adjacent cheek, with marked diminution of sensibility. When on the thumb it may remain there or may ascend the forearm as far as the elbow. Wherever it is felt, it lasts for ten or fifteen minutes, and then the headache begins, usually at the back of the head, and comes forward.

In another patient, a woman of 41, the hemianopia was sometimes lateral and sometimes transverse; the lateral loss did not extend to the middle line of the field, but the transverse loss reached the horizontal mid-level. If she looked at the middle of a clock dial, everything below the middle was indistinct. There was also numbness in the arm, slowly ascending and going to the lips and mouth on that side. When this was on the right side, loss of speech occurred also before the headache.

In young children sudden symptoms are sometimes seen, with headache, pyrexia, and general aspect of illness, often with vomiting. The symptoms cause a fear of acute meningitis, but after one or two days they rapidly pass away. For example, a boy, aged 9, had suffered since the age of 6 from two or three such attacks about every

six months. Each began with frontal headache for an hour; then extreme sleepiness came on, with vomiting at intervals. The temperature rose to 101° or 102°; the tongue was much furred, but after thirty-six or forty-eight hours all the symptoms passed away. There was a strong double family history of gout. The attacks generally seemed to be excited by some indiscretion in diet. I doubt not you will remember such cases, which come chiefly under the notice of the practitioner rather than of the physician, and I should like to know whether you have not observed that they gradually acquire, as years go on, the characteristic features of true migraine.

At the other end of life the prodroma of migraine frequently occurs without, or with but slight, headache, and sometimes with more brief headache than occurs during middle life. Occasionally the loss of power seems to be the chief symptom, and in these cases the headache is generally so slight as not to attract special attention. With many patients an error in diagnosis readily occurs in a first attack of this character, although another one is less likely to be mistaken. The weakness may be considerable. In one patient the attack came on when on a journey, and for an hour he walked with great difficulty. If we assume that vasomotor spasm is the cause of the prodroma, we may regard arterial spasm in the motor region as a sufficient cause of the loss of power.

The same conclusion was reached by Dr. Langwill of Leith regarding two cases of this character in late life, in which symptoms quite like those of a grave organic lesion passed away after an hour's duration. Each patient had other similar attacks.²

Recovery may not always occur, even if the vasomotor hypothesis is correct. The arterial contraction prevents sufficient blood reaching the region of the brain to maintain its function. When the blood state favours rapid thrombosis this may occur in the vessel so as to preclude the return of the circulation, and enduring thrombosis, with all its consequences, may maintain the loss of function as permanent hemiplegia. Indeed, there is some danger of this in earlier life if any change in the blood promotes its coagulation. A woman of 29 had been subject to migraine as long as she could remember, always on the right side of the head. During the fourth month of her second pregnancy an attack of her customary pain was followed by left-sided weakness, with ataxy of the hand, permanent left hemianopia, and impairment of sensibility on the left side. Pregnancy often involves an increased proneness to blood coagulation; there was no heart disease or albuminuria.

Migraine abounds in problems of interest, but I have striven to confine your attention to the points on which additional and extended facts are much needed. A consideration of the cases I have mentioned will show how numerous and various are these features in every case.

If these are not at first evident to you, I shall be only too glad to have an opportunity of pointing out the details on which any case may add to our knowledge, on information as to the general character of the premonition. The task is not easy, for the prodroma is brief and ever changing, and observation needs the perception of another person; but it is worth an effort and will reward the trouble it occasions.

I may add another word regarding treatment. The benefit from nitroglycerine and strychnine, although often most conspicuous, is not invariable. Cases in which vasomotor disturbance is well marked externally sometimes derive no benefit. Why this should be the case it is not possible to say. Bromide taken regularly may then have more effect, or a small, long continued course of salicylate. For the relief of attacks which are developing, a dose of antipyrin has often a quick influence, or Hochst's fused combination of antipyrin and caffeine (migrainin), or a similar preparation made by Martindale of antipyrin fused with salicylate of caffeine (migralgin). Nitroglycerine may conveniently be given in the form of the 1 per cent. solution, liq. trinitrini, but the mixture containing it must be kept acid. It may therefore be usefully united with a digestive tonic. Dyspepsia is common in some of those who suffer from migraine, and an error in diet may give rise to an attack some time after the previous one.

An Address

ON

THE DIAGNOSIS OF SYPHILITIC DISEASES OF THE NERVOUS SYSTEM.

DELIVERED AT THE CLINICAL AND PATHOLOGICAL SECTION OF THE BIRMINGHAM BRANCH OF THE BRITISH MEDICAL ASSOCIATION, ON FRIDAY, APRIL 30TH, 1909.

By F. W. MOTT, M.D., F.R.C.P., F.R.S.,

PHYSICIAN TO CHARING CROSS HOSPITAL, LATELY SENIOR TO THE LONDON COUNTY ASYLUMS.

ALTHOUGH syphilis is directly or indirectly responsible for a large number of organic diseases of the nervous system and it is a useful practice based upon the results of experience to treat a large number of cases of disease of the nervous system by antisyphilitic remedies, yet it is well to bear in mind that in such a widespread disease as syphilis, coincidence as well as cause is of very frequent occurrence. Therefore, in making a diagnosis we have to determine the question whether the fact that the patient has had syphilis, or even presents at the time of examination signs of active syphilitic lesions, is a coincidence or bears a direct or indirect causal relationship to the nervous symptoms for which he is consulting you. In many cases, especially in women, there may be no history of syphilitic infection and no signs on the body, and yet the character of the disease may clearly point to the possibility or even the certainty that it is of syphilitic origin; or it may happen that without a history or signs of syphilis a nervous affection may arise in an individual, which after antisyphilitic treatment ends by cure, arrest, or amelioration, but it does not necessarily follow that the disease was syphilitic, for we do not know what would have happened in the way of improvement if no drugs had been administered; in fact we cannot be sure whether it was an example of coincidence or cause.

A person suffering with an affection of the nervous system, whose blood gives a positive antigen reaction, is much more likely to be suffering from a syphilitic affection than one who has had syphilis but whose blood does not yield the reaction; for it is an indication that the syphilitic virus is still active, and therefore capable of producing true syphilitic lesions of the nervous system. An examination of the cerebro-spinal fluid in such a case will afford most valuable evidence not only as to whether the disease of the nervous system is post-syphilitic or not, but whether it is one of true syphilitic inflammation or of a degenerative parasyphilitic nature. Such evidence is of vital importance, for, in the case of the former, mercury, rapidly but judiciously administered, may be followed by a complete cure, whereas in the latter it will do more harm than good. I will cite a case that was recently under my care.

A woman, aged 34, was admitted to Charing Cross Hospital said to be suffering from tabes. She had shooting pains in the legs, unsteadiness in gait and station, a feeling of the soles as if walking on cork, unequal pupils which reacted sluggishly to light and to accommodation, pain and cramp in the muscles of the legs, absent knee-jerks, patches of anaesthesia on the legs, and a belt of thoracic anaesthesia with girdle sensation. After inquiring into the history and finding that she had suffered with headache and squint, that the knee-jerks which were absent on admission had returned a few days later, I came to the conclusion that this woman, with a probable duration of infection of not more than four years, was suffering really from pseudo-tabes, the result of syphilitic meningitis, especially as she told me that she had had a little stiffness in the neck, and I then obtained Kernig's sign. Lumbar puncture was performed, and 390 lymphocytes per c.mm. were found—an enormous number for tabes dorsalis. This large number of lymphocytes could only be accounted for by a widespread active gummatous change in the meninges. She was placed on mercurial inunction. The symptoms began to clear up rapidly, and a fortnight later the lymphocytes had fallen to 70 per c.mm., and at this time was tested by the Wassermann method, and found to give a negative reaction for both antigen and antibody. Unfortunately, blood was not tested on this or future occasions. A fortnight later the cerebro-spinal fluid was examined and only 20 lymphocytes per c.mm. were found, the patient being almost well. A fortnight later still, there were no lymphocytes, and the fluid was negative to the Wassermann reaction. The patient was quite well; the pains, anaesthesia, and unsteadiness had entirely disappeared.

It is of the greatest importance, therefore, to be able to decide whether a syphilitic patient is suffering from the immediate effects of the syphilitic virus on the enclosing, supporting, and vascular structures with secondary effects on the nervous structures, or from the remote effects of the syphilitic poison upon the bio-chemical stability, and therefore durability, of the nervous elements themselves. In the former case the nervous elements are secondarily irritated, damaged, or destroyed at random, although, for anatomical reasons, there are certain seats of election, the onset is more or less sudden, the symptoms are obtrusive and contrast markedly with parasyphilis, in which the onset is insidious, progressive, and of slow evolution. We shall see that examination of the blood and the cerebro-spinal fluid will often enable a decision to be arrived at as to which group of post-syphilitic affections the patient is suffering from. The sooner the nervous affection follows the primary infection the more likely it is to be syphilis of the nervous system; the longer the interval the more likely it is to be parasyphilis, but exceptions occur, especially to the former rule. It is much more common for tertiary syphilitic lesions of the nervous system to arise very long after the primary infection than for tabes dorsalis or general paralysis to occur within a few years of infection. There is no period from the appearance of the primary sore onwards to the end of life in which true syphilitic lesions of the nervous system may not occur.

The first point to decide is whether the nervous symptoms from which the patient is suffering are the direct result of the syphilitic virus upon the membranes, the blood vessels and their sheaths, with secondary degeneration of the nervous elements (for example, (1) Gummatous meningitis—cerebral, cerebro-spinal, spinal; (2) localized gummata, single or multiple, obliterative arteritis) or are the symptoms those of tabes or general paralysis? It is not always easy to decide, but it is well to bear in mind that the shorter the period which has elapsed between the primary infection and the onset of the symptoms the more likely it is to be due to the action of the syphilitic virus; it is very unusual for a generalized syphilitic meningitis to commence after the lapse of five years from primary infection; quite one-half of the cases manifest symptoms within the first eighteen months, in some the symptoms are obvious with the appearance of the roseolar rash, and a few cases have occurred when the primary sore was yet unhealed. A very different order of things to tabes dorsalis and general paralysis, for in these diseases it is very rarely that symptoms occur in less than four years after infection, and the average time is ten years.

In the case of active syphilitic meningitis, arteritis, and gummata, all of which conditions may occur simultaneously, successively, or progressively over the whole cerebro-spinal axis, the blood will most probably give a positive antigen reaction, the cerebro-spinal fluid will exhibit a great increase of lymphocytes and albumen, but it may give neither antigen nor antibody reaction. The administration of mercury will cause the disappearance of the antigen serum reaction, the disappearance of the lymphocytes from the cerebro-spinal fluid, and the cure, amelioration, or arrest of the symptoms if the disease has not been allowed to progress so far as to lead to thrombosis of vessels and destructive ischaemic softening of the cerebro-spinal nervous substance. In the case of parasyphilis, especially general paralysis, there is a different reaction, the blood serum giving the antibody reaction; the cerebro-spinal fluid both in tabes and general paralysis exhibits lymphocytes and shows the presence of albumen.

CLINICAL DIAGNOSIS.

Neurasthenia.

A neurasthenic who has had syphilis, and who is suffering with irritability of temper, headache, insomnia, lassitude, loss of memory, who has occasionally difficulty in finding words to express his thoughts, complaining of migrainous or vertiginous attacks and of various cutaneous sensory disturbances, in the form of anaesthesia or paraesthesia, who is hypochondriacal and depressed, who has a mortal dread of softening of the brain, from which some

friend of like habits and history has suffered, whose knee-jerks are exaggerated, and whose physiognomy exhibits a wearied, hypotonic, anxious condition, with lack-lustre eyes, will naturally arouse in the mind of the practitioner the possibility of the patient being in the prodromal stage of general paralysis. Examination of the pupils and of the cerebro-spinal fluid with negative results, in conjunction with the absence of any signs of dementia, will usually enable him to decide in favour of neurasthenia and to give a favourable prognosis.

Pseudo-General Paralysis.

Pseudo-general paralysis (diffuse syphilitic brain disease) is sometimes termed syphilitic general paralysis. I think that this is an unfortunate term to use, because general paralysis is of syphilitic origin and yet is incurable by antisymphilitic remedies. Diffuse syphilitic brain disease is not a primary neuronic decay, but a widespread chronic inflammatory process affecting the enclosing, supporting and nutrient structures, due directly to the action of the syphilitic virus; instead of occurring, as a rule, many years after infection, the most serious cases commence within the first four years after infection, therefore the average age incidence is some years below that of general paralysis.

The early diagnosis of *diffuse cerebral syphilis* is of the most vital importance, for it is amenable to antisymphilitic treatment, which if adopted in its early stages arrests or ameliorates, but occasionally a partial cure, or even a cure may be hoped for. It is, therefore, essential to know what are the diagnostic differences of general paralysis and diffuse cerebral syphilis. It is rarely that true general paralysis is associated with permanent coarse obtrusive paralyses; in fact the term "paralysis" expresses the condition more truly. On the other hand, diffuse syphilitic brain disease is very liable to be followed by paralyses of all kinds.

Still, cases of universal syphilitic *endarteritis cerebri* accompanied sometimes by a gummatous meningitis and gummatous cerebral tumours for some time present no evidence of coarse paralyses, and not infrequently such cases are admitted to the asylums and are more often than not diagnosed as general paralyses; accordingly they are not treated with mercury. At the autopsy one recognizes a disease which is of a totally different pathological nature; the brain is not wasted, the convolutions are not shrunken, if anything they are rather flattened, as if there had been an excess of intracranial pressure. The patient was undoubtedly demented, and, although there were no signs of paralysis, he was weak, shaky, and tottery in gait. But was the mental condition like that of a typical paralytic dement? had he no physical signs or subjective symptoms during life which would point to his suffering from diffuse cerebral syphilis? These have been the questions I have many times asked myself when making autopsies on such cases. First of all many of these patients have signs of syphilitic skin lesions, often scars of gummata. The friends will tell you that they have for some time complained of severe headache, often worse at night. If accompanying the dementia they have had coarse paralyses, blindness or other obtrusive symptoms, coming on more or less suddenly, and with remissions and regressions, there is but little difficulty in diagnosis; but where the symptoms are mainly demential the diagnosis is not so easy, and necessitates a comparative knowledge of this form of dementia and the dementia characteristic of general paralysis. I now attempt to indicate the main points which will enable a differential diagnosis to be made. "The dementia of syphilitic brain disease is partial; it is unequal and elective in its attack; it compromises certain forms of psychic activity, memory, association of ideas, energy and capacity for mental work, rather than diminishing intelligence as a whole. It does not alter so profoundly the character and personality of the individual, nor in the great majority of cases does it destroy the patient's idea of his past and present state, nor that of orientation in time and space. He still possesses the *autocritical* faculty, and is more or less conscious and disturbed by his mental deficiency" (Dupré). It is not necessary to inquire of others whether he has had lapses of consciousness or signs of torpor and apathy, or fits of depression, for he himself will usually tell you.

"According to my experience, based upon the results of a large number of post-mortem examinations, there is always associated periarthritis, endarteritis, peripneumonitis, encephalitis, and myelitis; the neoplastic formation extends from without inwards along the perivascular lymph sheaths, and is never entirely limited to the membranes; it affects, more or less, the whole cerebro-spinal axis.

(1) *Diagnose différentielle entre la Dénence Paralytique et les autres formes des Démences acquises.* Rapport IV, 1er Congrès Internationale de Psychiatrie, etc., Amsterdam, 1907.

From a clinical point of view syphilitic dementia is accompanied by numerous mental and bodily symptoms. The mental symptoms comprise states of excitement and depression more sudden and accentuated than general paralysis; there are disturbances of consciousness in the form of somnolent, drowsy, semi-comatose conditions from which the patients emerge, again to relapse, and such remissions are especially significant. In the intervals there is not the same intellectual and affective deficiencies as in general paresis, nor does the same apatheticism, moral optimism, suggestibility, mobility, and automatism obtain as in general paralysis. The accompanying bodily troubles are coarse and obtrusive, and due to focal disseminated lesions in the brain and spinal cord, causing apoplectic and epileptiform seizures, followed by aphasia, paraphasia, apraxias, hemiplegias, monoplegias, paraplegias, triplegias due to affection of cortical centres and their projection systems: or paralyzes and sensory troubles from affection of cranial nerves and their nuclei of origin arise. The clinical picture may be slow in its evolution; it is irregular, variable, and proceeds by fits and starts, with prolonged and sometimes indefinite periods of arrest. It is often a stationary dementia, and under the influence of mercurial treatment it may undergo regression. True general paresis may occasionally—but rarely, according to my experience—supervene on such cases of regressive or arrested cerebral syphilis. The syphilitic dementia may in rare instances be accompanied by a tabes dorsalis, and we may think we have a case of tabo-paralysis, or there may be a pseudo-tabes associated with pseudo-general paralysis. When hereditary syphilis produces in a child or young adult a diffuse meningo-encephalitis, it may simulate general paralysis.

The best criterion lies in the mode of evolution of the dementia and paralysis. The evolution of general paralysis is slow, insidious, and progressive towards marasmus and death. Syphilitic dementia, especially if it be treated, remains stationary or tends to regression, ending in a state of acquired imbecility, of which the history affords the clue. In my experience dementia from congenital syphilis is much less frequently met with than juvenile general paralytic dementia.

Recent investigations have shown that tuberculosis may produce in children diffuse encephalic changes of a chronic inflammatory and hyperplastic nature, terminating in a diffuse nodular sclerosis of the brain. These lesions cause mental enfeeblement, imbecility, and idiocy.

Arterio-sclerosis.

Syphilis is probably the most important factor in the production of arterio-sclerosis, especially cerebral arterio-sclerosis. Consequently a patient who has had syphilis may present signs of general arterio-sclerosis in which the vessels of the body generally, and of the brain and kidneys in particular, may suffer. Toxic conditions of the blood may arise in consequence of the latter affection; owing to the renal inadequacy, and probably also the diseased conditions of the vessels of the brain, uraemic symptoms may arise in a person who is suffering with mental symptoms caused by the disease of the cerebral vessels and the altered conditions of the blood. The symptoms of uraemia—namely, headache, pyrexia, twitchings, epileptiform seizures—may simulate the symptoms and seizures of general paralysis. There are, however, points of difference which will enable a diagnosis to be made. In such a case examination of the heart and arteries and of the urine would afford information. The pupils in uraemia may have a sluggish reaction to light, but they are rarely unequal or irregular. Very probably examination of the fundus will show retinitis, haemorrhages, and arterio-sclerosis of the retinal arteries, causing thickening of the walls, which appear like silver wires; consequently the veins as they pass over the thickened arteries often show a kink. The patient is usually over 50 years of age. The cerebral symptoms are often characterized by a progressive dementia and paralysis, but there are many points of difference, both in the mental and motor symptoms. From the psychological point of view, the dementia of cerebral arterio-sclerosis is a partial, unequal loss of mind. The patient becomes irritable, suspicious, and even dangerous to himself and others; there is exaggeration of emotivity, and various psychopathic reactions complicate the intellectual decadence; but, unlike general

paralysis, the patient retains his notions of personality and the faculty of auto-criticism, and is therefore more or less conscious of his loss of memory and mental enfeeblement. From a clinical and evolutionary point of view the dementia of arterio-sclerosis is associated with varied and innumerable paralytic symptoms appearing after seizures or in sudden attacks, and due to the capricious, random affection of the different arteries of the brain supplying different functional territories. The arteries may be so thickened as to interfere with a proper supply of blood to various areas of the brain, or they may become occluded by thrombosis, in which case disseminated areas or foci of inflammatory softening and necrosis may result. The symptoms naturally vary according to the seat and extent of the lesions. When the anterior cerebral is affected a seizure may occur, and, owing to the paracentral lobe being destroyed on one or both sides, a leg monoplegia or paraplegia may result accompanied by disturbance of spontaneous psychic activity and of memory; in affection of the middle cerebral, there results hemiplegia, aphasia, apraxia, paraphasia, word deafness, word blindness, and dysarthria; in the posterior cerebral, hemianopsia, psychical blindness, and disturbances of topographic orientation. If symmetrical areas are affected by arterial ischaemia, or the projection fibres proceeding from those areas in the internal capsule undergo necrotic softening, paralyzes of a pseudo-bulbar nature—for example, dysarthrias and difficulty of swallowing, etc.—may occur. One fact obtains in all cases: it is a parallelism between the depth of the dementia and the extent and degree of destruction of the cerebral cortex. Besides, we may have other less serious bodily disturbances resulting from arterio-sclerosis of the cerebral vessels which might especially be thought to indicate general paralysis—namely, apoplectic attacks followed by hemiparesis, dysarthria, difficulty in swallowing, disorders of psycho-reflex activity of speech, of mimicry, forms of apraxia and asymboly combined more or less with paretic-spastic symptoms. The character of the physiognomy in the case of organic dementia differs from that of general paralysis by the predominance of mimic disturbance over intellectual deficiency. In the former disease the patient shows a marked emotivity, readily bursting into tears or laughter, and not infrequently there is facial asymmetry of spasmodic or paralytic origin. These cases of arterio-sclerosis producing progressive dementia, paresis, or paralysis and pseudo-bulbar speech troubles are sometimes erroneously diagnosed as general paralysis of the insane, especially when accompanied by seizures, mental excitement, or depression and delusions. I have, however, seen typical general paralysis accompanied by general arterio-sclerosis; but, as a rule, the cerebral arteries in general paralysis are not thickened, and examination of the fundus rarely shows any noteworthy changes unless it be a case of tabo-paralysis, when optic atrophy is very frequently discovered. In a number of cases which I have examined of arterio-sclerosis I have found multiple softenings in the internal capsule and basal ganglia caused by disease of the lenticulo-striate arteries. These lesions account for the emotivity, mimic disturbances, dysarthrias, and pseudo-bulbar affections.

Chronic Alcoholism.

Cases of chronic alcoholism in which there is a history or signs of syphilis frequently offer many difficulties in the matter of diagnosis. They do so for many reasons: first, because many paralytics in the early stages of the disease take to drink. The symptoms they present are largely due to the effects of the intoxicant, and they are certified and sent to the asylum, where the diagnosis of *mania a potu* is made. The true nature of such a case declares itself after the effects of the alcohol has had time to wear off. I once saw a man who upon admission saw black devils come and perch on his nose and fill his nostrils with stinking things. He had been drinking heavily. A week later, when the effects of the alcohol had passed off, he had a marked euphoria, and when asked whether he still saw black devils that came and perched on his nose he said that they were angels with wings of gold, and that they put sweet perfumes in his nostrils.

Hallucinations, especially of vision and of a terrifying nature, are common in alcoholism; they are not common in general paralysis uncomplicated by alcoholic intoxication.

tion. The dementia of alcoholism is characterized by the predominance of the moral affective defects over the intellectual, by a degradation of the ethical sense, deterioration of will, and the tendency to delusions of persecution, jealous suspicion, and violent motor reactions, rendering them dangerous to themselves and others. The psychic activity is confused rather than destroyed. There is deficiency rather than absence of memory.

Alcoholic Polyneuritic Psychosis (Korsakow's Disease).

The clinical picture of a severe case of the disease is not unlike that of general paralysis in its final stages. It is commoner in females than in males. The patient, prostrate, bedridden, and emaciated, with contracted limbs and suffering with bedsores, lies oblivious to her surroundings; roused to reply to questions, only incoherent responses are obtained. Such a condition may well be termed *pseudo-general paralysis*. Frequently a definite diagnosis cannot be made unless the case be watched; if this be done, occasionally at intervals the mind may appear to be relatively clear in Korsakow's disease. The definite signs and symptoms of polyneuritis may be present. When the symptoms of Korsakow's disease are confined to loss of memory and mental confusion the diagnosis is more difficult. Auto-criticism may still be present in a patient suffering with Korsakow's disease; consequently, when confronted by her mental shortcomings she betrays astonishment and even alarm in her facial expression. The general paralytic, having lost the faculty of *auto-criticism*, is self-satisfied, and the expression is one of foolish contentment or of apathetic indifference. Both diseases are characterized by *pseudo-remembrance*: but in general paralysis there is fantastic fabrication, whereas in Korsakow's disease the content of the pseudo-remembrance is more or less of a probable nature and usually related to some past experiences in the patient's life. For example, a woman suffering with alcoholic dementia, named Gloster, was certified as suffering from delusions of grandeur. "She said she was the Duchess of Gloster." After she had been in the asylum some time and the dementia was passing off, I questioned her in reference to the delusion in the certificate. She stated: "My husband was humpbacked; his name was Gloster, and his pals called him the Duke of Gloster. If he was the duke, surely I had a right to call myself the duchess." She admitted that it was foolish on her part to have done so. A very characteristic delusion of this disease is that there is a baby in the bed. In Korsakow's disease there is complete disorientation: the patient has no idea of time or place or of the identity of persons. In general paralysis, on the other hand, there is incomplete disorientation: the patient still recognizes familiar surroundings and persons with whom she is habitually brought in contact. The loss of memory and receptivity is transient or temporary, but it is more complete for the time being than in general paralysis; the *amnesia* of general paralysis may not be so marked at first, but it is progressive and continuous. The existence of the Argyll Robertson pupil and of irregular, unequal pupils as permanent phenomena would decidedly point to general paralysis rather than Korsakow's disease. The cerebro-spinal fluid in the case of Korsakow's disease would be negative as regards the antibody reaction and lymphocytosis; therefore in all doubtful cases lumbar puncture should be performed and the cerebro-spinal fluid examined.

Dementia Praecox.

The age, mode of onset, and evolution of this disease is unlike that of general paralysis, except in the juvenile form. In 80 per cent. of the cases of dementia praecox the mental symptoms occur before the age of 25. There is usually a strong hereditary history of insanity, and no history or signs of congenital syphilis. General paralysis is a disease which on an average does not commence until ten years after infection; therefore the most frequent period for general paralysis to occur is not adolescence, but the prime of life. Occasionally, however, I have seen young women admitted to the asylum with *dementia paralytica* in whom the mental affection commenced at a relatively early age. Inquiry into the history often shows that they were prostitutes or had come from a refuge home, or a history of congenital syphilis was either certain or probable. Dementia is not the earliest sign of this affection, but hallucinations and fragmentary delu-

sions; the Argyll Robertson pupil is not present, the pupils are not unequal, and as a rule not irregular. If there is any doubt, the diagnosis can at once be settled by examination of the blood and cerebro-spinal fluid by the Noguchi and Wassermann methods, and by cyto-diagnosis of the cerebro-spinal fluid. Twenty successive cases of dementia praecox were examined by Drs. Harper Smith and Rae Gibson in the laboratory, and in every instance the result was negative.

Disseminated Sclerosis.

The typical insular sclerosis of young adults should not be mistaken either for general paralysis or multiple syphilitic brain disease, although cases of multiple focal patches of sclerosis, the result of syphilitic arteritis, thrombosis and ischaemic softening, in many respects resemble that form of insular sclerosis the cause of which is at present unknown. The difference in the clinical symptoms and the evolution of the disease to general paralysis in most cases suffice for a differential diagnosis; but if there be any doubt, examination of the cerebro-spinal fluid and blood with negative results will serve to exclude general paralysis. I have occasionally seen cases of multiple syphilitic focal lesions, the result of syphilitic arteritis, in comparatively young women, in whom there was scanning speech, increased deep reflexes, spastic limbs, Babinski's sign, and nystagmus. One case in particular I have in mind. At the autopsy I found an old syphilitic arteritis with a focal sclerosis in the pons; there was also degeneration of the ascending and descending long tracts of the cord. The patient showed no signs of syphilis on the body, but she may have had it, as she was unmarried, and yet had had a child. It is probable that such a case might have given the serum reaction, and possibly the cerebro-spinal fluid also would have yielded a positive result.

Cerebral Tumours.

Cases of cerebral tumour without motor or sensory troubles are not infrequently sent to asylums, and, according to my experience, they are as often as not called "general paralytics." Examination of the fundi in most cases would have revealed optic neuritis, a condition never found in general paralysis, although it may occur in syphilitic brain disease; but as a rule, according to my experience, syphilitic gummata and syphilitic meningitis do not produce the same degree of swelling of the disc that non-syphilitic tumours do; very much, however, depends upon the situation and the rapidity of growth of the tumour. Large slow-growing tumours of the frontal lobe occurring in men at the prime of life and with a history of syphilis and drink may be especially difficult to differentiate from the slow demential form of general paralysis; especially is this so when the tumour destroys the left frontal lobe and irritates the adjacent motor cortex, as it would cause epileptiform seizures and speech affections from the involvement of Broca's convolution. I have recorded a case in vol. iii, *Archives of Neurology*, of such a nature, in which the pupils were unequal, there was no optic neuritis, no vomiting, no severe headache. He was seen later by Dr. Percy Smith, who agreed with me that it was a case of general paralysis; he was then certified and sent to the asylum. The attendants there said he was a general paralytic, but not an ordinary case. Not infrequently the effect of treatment by mercury injection is associated with diminution of the swelling of the discs, and even when there is no history of syphilis this result would point to its being the probable cause. I recently saw a woman in one of the London County Asylums, and had her transferred to Charing Cross Hospital. Mr. Collins found five diopeters of swelling in each disc. After a course of mercurial treatment the swelling went down rapidly to two diopeters, and from being unable to read large print, she could read quite small, the headache ceased, and the vomiting no longer occurred. The cerebro-spinal fluid of this case did not give the Wassermann reaction, although it contained a considerable excess of lymphocytes; but then we know that in only about 25 per cent. of cases of syphilitic brain disease does the cerebro-spinal fluid give a positive antibody result. Lymphocytosis by itself is not sufficient evidence to prove that the disease is syphilitic, but the result of treatment combined with this makes it fairly certain that it was a syphilitic gumma that caused the symptoms in this case. When a gumma has gone on to

the later stages of necrobiosis and formation of dense scar tissue, as not infrequently happens in syphilitic neoplasms of the brain, the chances of successful treatment by mercury and iodide of potassium are more improbable. If epileptiform convulsions or epilepsy have become established, it is no proof, therefore, that it is not syphilitic because the fits do not cease after administration of anti-syphilitic remedies. I have seen quite a number of such cases which have been treated efficiently with anti-syphilitic remedies in which the fits continued, and which at *post-mortem* examination still showed an old caseous focus commingled and surrounded with dense scar tissue; consequently the treatment failed to produce resolution, and the symptoms of irritation had continued. The early diagnosis of a syphilitic gumma is therefore of great importance for successful treatment. A gummatous pachymeningitis giving rise to headache and pain on pressure, but without the general signs of increased intracranial pressure—namely, optic neuritis and vomiting—may occur. I have seen such cases with localizing symptoms, and one which I diagnosed during life in Hanwell Asylum was of interest, inasmuch as it failed to yield to anti-syphilitic remedies, but had it been transferred to the hospital it could have been treated surgically with almost certain success. (See *Archives of Neurology and Psychiatry*, vol. iv.)

General Paralysis.

It will be gathered that my object hitherto has been mainly to exclude from the diagnosis general paralysis, but in doing so I have alluded to most of the mental and bodily symptoms of this disease. Although grandiose delusions are very common in general paralysis, and occur in the majority of the cases, sometimes indeed persisting from the earliest period when the disease is diagnosed until the fatal termination, yet some cases of paralysis are associated with marked mental depression and hypochondriasis, while others are characterized simply by a progressive parietic dementia. Sir Alex. Morison, in his *Physiognomy of Mental Diseases* (1840) gives a very good clinical account of general paralysis, and remarks that Drs. Calmeil and Esquirol (he should have added Bayle) had given the disease the name of "general paralysis of the insane," but by the regulations of Bethlem Hospital cases of this description for upwards of fifty years have been excluded; nevertheless, patients in the early stage of the disorder, have been frequently admitted, and have undergone treatment for a limited time, so it is well known there. Thus he says:

When a patient is brought to the hospital expressing ideas of high rank or expectations, great abilities, extensive possessions or much wealth, particularly in articles of gold, with impaired memory and weak volition, or what may be termed infirmity of purpose, and at the same time has a slight difficulty and hesitation in speech, and an unsteady and tottering gait in walking, it is concluded that he labours under this formidable disorder in its early stages, and that there is little or no chance of his recovery.

Sir A. Morison, it may be remarked, was attached to Bethlem, and must have been aware of Haslam's description. But long before Haslam had differentiated this form of paralytic insanity, the keen observation of Hogarth had depicted inimitably some of its most characteristic symptoms in a scene in *Bedlam* of the *Rake's Progress*, 1735. I here reproduce two drawings (taken from this scene) from Morison's *Physiognomy of Insanity*, with the explanation, p. 279:

Upon these portraits Gilpin observes that the self-satisfaction and conviction of him who has discovered the longitude and

the mock majesty of the monarch are admirable; the latter deems himself worthy of a crown, and sits in an attitude of great pomp, viewing his wooden sceptre and wearing his paper crown with as much conviction of his dignity as any monarch in Europe. The mind of the other seems lost in thought, and Hogarth's peculiar genius appears in his having the geographer whose element is ranging the wide world closely mowed up in a corner.

What better example could one have of the loss of autocriticism to which I have referred so often as being so significant of parietic dementia? (See illustration.)

There are many types of general paralysis; but there are a few phenomena which are seldom or never absent: (1) progressive dementia affecting the mind in its totality usually accompanied by elation, motor activity and grandiose delusions, sometimes by depression, motor inactivity and hypochondriacal or persecutory delusions; (2) pupillary affection—the pupils may be unequal, they are generally irregular and react sluggishly or not at all to light, but react to accommodation; (3) progressive paresis with tremor, especially affecting the tongue and face muscles; (4) hesitant, tremulous, slurred speech with elision of syllables; (5) similar affection of the handwriting, and often even in the early stage of the disease, the subject matter denoting dementia and delusions combined with the tremor, the elision or repetition of letters and syllables, suffice for a diagnosis; (6) altered knee-jerks generally exaggerated, sometimes absent on one side, or on both sides without Babinski's sign or ankle clonus. When the above symptoms are present there is little difficulty in diagnosis, but in the earliest prodromal stage, sometimes termed "the medicolegal," there may be considerable difficulty in forming an opinion, and the most experienced authorities make mistakes. I shall, therefore, only point out some of the manifestations of this early prodromal period. A modification of character and conduct occurs, the patient may become depressed, irritable, ill-tempered, preoccupied, moping, and hypochondriacal; or he may become

unusually restless, active, and excitable, full of new ideas and schemes, neglecting his business, profession, and family; he may launch into speculations, purchase goods for which he has no use, or he may give himself up to immorality, and even depravity. At this period alcoholic abuse is very frequent; hence at the commencement of parietic dementia toxic disturbances frequently complicate the clinical picture, making the diagnosis more difficult. A hyperaesthesia sexualis is frequent, and the increased sexual desire, with impairment or loss of function, may lead to criminal acts which may bring him into the police courts. In this medicolegal period he may get into the police courts for acts of drunkenness, theft, attempted suicide, manslaughter, or homicide. The loss of control and impulsiveness is in a large number of cases aggravated by alcohol, so that he becomes a danger to himself and others; yet it is not uncommon at this period to find that the patient is not unconscious of his morbid state, and it may be very difficult to certify him, as he may apprehend the object of your visit and take care not to give himself away. As a rule, however, even in the early stage, he is not critical of his own conduct and behaviour; moreover, grandiose ideas are often easily revealed by suggestion; moral optimism and approval is frequent.

The most important somatic disturbances in the prodromal stage are apoplectiform, epileptiform, and congestive seizures. I have known many cases in which such attacks have preceded years the definite signs of dementia. There

attacks may be followed by transitory paralysis in the form of aphasia, hemiplegia, monoplegia, etc.

It is in cases of doubtful diagnosis that the pathologist can afford help by the employment of methods of examination of the blood and cerebro-spinal fluid, to which I fully referred in the Morison Lectures, but which I will briefly note again, for since I gave the lectures I have found these methods of great use in the diagnosis of several early doubtful cases of general paralysis.

EXAMINATION OF THE CEREORO-SPINAL FLUID.

The Wassermann-Neisser-Brück Method.

This test may be carried out in the following manner. It is necessary first to immunize an animal against the blood corpuscles of some other animal—for example, by injecting the blood corpuscles of an ox into the circulation of a rabbit. After several injections the blood serum of the rabbit becomes haemolytic to the blood corpuscles of the ox by virtue of the presence in the serum of an immune body *plus* the normal complement or cytase. The latter is removed from the serum after withdrawal from the rabbit by heating to 56° C. for thirty minutes. There is then left in the rabbit's serum the immune body, which by itself will not dissolve the red blood corpuscles of the ox. The addition, however, of a small amount of guinea-pig serum which contains complement will at once restore its haemolytic properties.

The actual experiment consists in mixing the serum or cerebro-spinal fluid to be examined in varying dilutions with a watery or alcoholic solution of the liver of a syphilitic fetus; a small amount of the serum of a guinea-pig is added, and the bulk made up to a constant volume (about 2 c.cm.) with saline solution. The series of tubes containing these mixed solutions are placed in an incubator at 37° C. for one hour, and then the sensitized corpuscles are added. By sensitized corpuscles I mean the washed corpuscles of the ox to which has been added the heated rabbit's serum. The mixtures are again placed in an incubator for two hours at 37° C., then removed and placed on ice overnight. The next morning the amount of haemolysis in each tube can be estimated. If, on the one hand, antigen (contained in the extract of the syphilitic liver) and antibody (in the serum or cerebro-spinal fluid) have been present they have united with the complement (provided by the guinea-pig serum), and no solution of the corpuscles will have taken place, because the complement has been fixed before the addition of the sensitized corpuscles. If, on the other hand, the antibody was not present in the serum or cerebro-spinal fluid, then the complement in the guinea-pig serum has remained free to act on the sensitized corpuscles, and to lead to their solution (haemolysis). A control experiment using normal serum or cerebro-spinal fluid—namely, one which contains no antibody—must be made at the same time.

In order to make the antigen test, the blood serum or cerebro-spinal fluid is used in place of the syphilitic liver extract, and tested in varying dilutions against a serum or cerebro-spinal fluid which has previously been proved to contain antibody in known amount.

The Noguchi Method.

A simple method introduced by Noguchi consists in boiling two parts of the cerebro-spinal fluid with five parts of a 10 per cent. solution of butyric acid in saline solution for a few seconds and then adding one part of a normal sodium hydrate solution and again boiling briefly. A flocculent or granular precipitate is obtained on standing in parasyphilitic affections, due to the presence of a globulin. The test is useful in distinguishing general paralysis from other forms of insanity not associated with meningitis-encephalitis.

Cyto-diagnosis.

The number of leucocytes present in the cerebro-spinal fluid may be estimated approximately by the following methods:

1. A drop of the fluid which has been previously well shaken is placed in the chamber of a Thoma-Zeiss haemocytometer and the cells allowed to settle. The number of cells lying over the 400 squares of the chamber multiplied by 10 will give the number of leucocytes in 1 c.mm. of the fluid.

2. The cerebro-spinal fluid is centrifuged and the supernatant fluid poured off. The residue is removed in a

capillary pipette, blown on to a slide and allowed to dry. Stained with Leishman or Jenner's stain the residue from a normal cerebro-spinal fluid will show at the most only two or three lymphocytes in the field with a magnification of 400 diameters, whereas in progressive parasyphilitic affections the lymphocytes are markedly increased in number.

An Address

ON

CHRONIC INTESTINAL STASIS.*

BY

W. ARBUTHNOT LANE, M.S.LOND., F.R.C.S.ENG.,

SURGEON TO GUY'S HOSPITAL; SENIOR SURGEON, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON.

GENTLEMEN,—I am very pleased to have this opportunity of addressing you on a subject that has afforded me the greatest interest, as I am most anxious to have the benefit of your opinion upon it, knowing that you will consider it with an open mind. I hope, however, that some of what I have written about it may not be completely unknown to you, and that it has possibly already received your attention and kindly criticism. Chronic intestinal stasis comprises the conditions arising in consequence of the progressive development of an imperfect or delayed functioning of the gastro-intestinal tract. While constipation is the most frequent objective evidence of unsatisfactory drainage associated with chronic intestinal stasis, it happens not uncommonly that there may be a daily evacuation. In some cases the motions may be abnormally frequent and loose. Therefore the character and frequency of the evacuations are by no means constant in this condition.

PATHOLOGY.

I will endeavour to describe what I consider to be its pathology.

1.

In the first place there is the dilatation and extension of the caecum into the true pelvis, associated with the development of retaining bands or mesenteries between its outer aspect and the adjacent peritoneum lining the abdominal wall. The caecum may become so distended that, after occupying the true pelvis, it ascends upwards from it.

2.

Secondly, there is the fixation of the appendix by retaining bands continuous with those holding up the caecum, and securing the appendix usually about its centre, sometimes by separate bands, and at other times by a band blended with the normal mesentery of the appendix. This band is continued by the proximal portion of the appendix, and forms together with it a retaining support helping to hold up the caecum, and oppose its descent from its normal position.

The drag exerted upon the caecum, upon the proximal part of the appendix, and upon its retaining band of peritoneum, produces a kinking of the lumen of the appendix at its point of fixation, since the distal portion of this structure is necessarily tilted abruptly upon its proximal segment. The degree and chronicity of this occlusion produce varying results, all of which are grouped under the heading of "appendicitis." The point of the abdominal wall to which the appendix becomes secured varies within wide limits, but it is usually anchored to the iliac fossa. If, however, it is fixed to the posterior wall or floor of the true pelvis, the appendix in the female finds itself in dangerous proximity to the right ovary which is affected by any inflammatory change in the appendix, while during menstruation the engorgement of the ovary and adjacent structures accentuates any trouble in the appendix.

Though surgeons refuse to recognize the causation of these bands obstructing the appendix, they know that adhesions exist about it very constantly, and they are always very ready to avail themselves of these adhesions as an excuse for removing the appendix when they have

* Delivered before the American Surgical Association at Philadelphia June 3rd, 1909.

opened the abdomen on a wrong diagnosis of disease in some other organ, such as stone in the gall bladder, duodenal ulcer, stone in the kidney or ureter, etc. At the operation, when the incorrectness of the diagnosis is plain to all, they satisfy their own conscience, the medical attendant, and the patient and his friends by removing an appendix anchored in the manner I have described.

3.

The ascending colon is anchored to the peritoneum lining the abdominal wall external to it by similar bands, while the hepatic flexure is drawn upwards and outwards to an abnormally high level by the presence of bands of peritoneum of considerable density.

4.

The transverse colon forms a loop the convexity of which reaches in some cases into the pelvis, where it struggles with the caecum for priority of occupation.

Bands of peritoneum bind the convexity of the transverse colon to the adjacent ascending and descending segments of the colon. Above these viscera are bound directly together by newly-developed adhesions, but below they are connected by an acquired mesentery.

5.

The splenic flexure and descending colon present changes similar to those described on the right side.

In the large bowel generally the strain exerted by restraining bands may so control it as to reduce its lumen very materially at one or more points.

6.

The changes in the sigmoid are perhaps the most striking and obvious. They arise in precisely the same manner as those already described. Nature makes an effort to convert the mobile loop which would attempt to occupy the pelvis into a narrow fixed straight tube connecting the descending colon and rectum.

This is effected by the development of little bands which pick up the outer aspect of the meso-sigmoid and secure it to the adjacent peritoneum. This process continues till a proportion of the outer wall of the sigmoid itself is secured to the iliac fossa, and the tube is rendered fixed and straight, all evidence of the original loop having disappeared. This ideal condition does not always exist, since the bulk of the mesentery may not have been grasped securely by the newly-developed adhesions before the ends of the loop have been secured and approximated by them. Consequently a very considerable dilatation of the sigmoid results, and when it is completely obstructed it is called a volvulus.

The fixation of the sigmoid by these acquired adhesions may be irregular, and obstruction may occur at one or more points in its length.

Unfortunately for the left ovary it lies in immediate relationship with the meso-sigmoid, and it very frequently indeed becomes involved and fixed in the acquired adhesions. In some cases it appears as if the ovary is merely anchored to the contracting meso-sigmoid by adhesions, while in others the ovary may be completely surrounded by and included in the altered meso-sigmoid.

7.

The fixation of the left ovary is very detrimental to that structure since it is followed sooner or later by a cystic change in that organ. In some cases the ovary may be infected with a chronic inflammation, or suppurative may result in it necessitating its removal. Very rarely the sigmoid may be so much involved by the process that it may be necessary to resect a portion of it also.

The cystic ovary, completely surrounded by the adhesions, may after a time again become mobile in a cavity developed in them and later may escape from it. It then ceases to have any apparent connexion with the adhesions in which it was embedded except in so far as the association of an anchored sigmoid and a cystic ovary is observed to exist.

8.

The ileum is very thin-walled and flaccid. If its termination is drawn upwards so as to expose the under surface of its mesentery the peritoneum forming its

posterior surface is picked up in puckers precisely like the meso-sigmoid but not so effectually. This is clearly with the object of helping to support the loaded caecum and oppose its displacement.

9.

The stomach is dragged downwards by the pull exerted upon its convexity by the depressed transverse colon, while the pylorus and first portion of the duodenum are bound to the under surface of the liver and often to the cystic duct and gall bladder. The stomach is dilated apparently because of the kink effected at the exit by the downward drag on the convexity of the stomach and the resistance offered by the adhesions binding the pylorus and duodenum to the liver.

Owing to the very different construction and mechanics of the abdomen and of the viscera in the sexes the mode of anchoring of the pylorus and duodenum differs somewhat. I believe that this variation is responsible for the greater frequency of duodenal ulcer in the male and of gastric ulcer in the female.

The posterior surface of the stomach is not infrequently adherent to the peritoneum covering the pancreas, etc.

10.

The gall bladder is generally full of bile, and gall stones are not infrequently present. The development of gall stones may be consequent on the stagnation of bile in the gall bladder whose evacuation is impaired by the drag upon it or upon its duct by the anchored duodenum and pylorus and by the prolapse of the liver itself. Women being much more frequently affected by intestinal stasis than men suffer more often from gall stones. It is a noteworthy fact that, while gall stones do not form in cases of intestinal stasis in which loss of flesh results at an early period of life from toxic absorption, they do so very readily in stout women in whom intestinal stasis develops in a marked degree comparatively late in life.

11.

The breasts show changes which vary from a recurring mastitis affecting the upper and outer segments of the breasts, and especially of the left, to a definite cystic degeneration involving the whole of both breasts. These degenerated breasts are very susceptible to the development of malignant disease.

12.

The kidneys are mobile.

13.

There is very little fat.

14.

The skin is stained and inelastic.

15.

Respiration is chiefly diaphragmatic.

16.

The circulation is bad, as evidenced by the coldness of the extremities.

17.

The muscles are very friable and small in bulk.

SYMPTOMS.

The symptoms produced by this condition of things are due in part to the interference in the normal functioning and is expressed by pain, and in part to the absorption of poisonous material, and is evidenced as toxæmia.

While toxic symptoms may exist without pain, pain has always associated with it definite evidence of auto-intoxication. I would just mention that many of the objective evidences of auto-intoxication, such as pigmentation of the skin and bad-smelling perspiration, are much influenced by the colour of the hair. In light-haired people a very advanced condition of poisoning may exist without the presence of these symptoms, while in dark-haired people these evidences appear at an early period.

Pain is due apparently to the distension of a portion of the bowel with faecal contents and their gaseous products or by the passage of faecal material through it. For instance, the distension of the caecum is a frequent and distressing symptom.

Pain about the hepatic and splenic flexures, both in front and behind, results from the obstruction which exists at those points and from the drag or strain upon the retaining bands by the loaded bowel in the erect posture of the trunk.

Pain in the sigmoid segment may be due to the difficulty in forcing the contents through a fixed, straight tube of diminished calibre, length, and elasticity whose mucous membrane may be gorged, inflamed, or even ulcerated, or to the distension of a loop or loops placed at a mechanical disadvantage by irregular anchoring by adhesions. Pain also results from the distension of the stomach, and also of the small bowel because of its delayed functioning.

Pain in the fixed left ovary is frequently a distressing symptom, especially at the periods. The fixation of this irritated organ renders it very tender on pressure, especially if examined bimanually, since it cannot readily avoid the pressure of the fingers as does a mobile ovary. Apart from this, there are the mechanical symptoms which ensue from the progressive development of the cystic condition of the ovary, which is now found to be more frequently malignant in structure than was supposed.

Degenerative cystic changes in the breast are very commonly present in a varying degree in certain cases of chronic intestinal stasis. This change is usually first observed in the upper and outer segment of the left breast, and later in the corresponding area of the right breast.

In the young unmarried woman chronic mastitis which is accentuated at the periods is very common. It affects the same areas of the breasts as does the cystic change which appears later. In a number of patients on whom I have operated for chronic intestinal stasis one or both breasts had been removed for cystic degeneration. This condition has been called Schimmlbusch's disease. I have been much struck by the fact that these degenerative conditions do not arise in the breasts of women having regular intercourse, however toxic they may be, while they develop very rapidly on its cessation. How far the mechanical impairment of the sexual apparatus here referred to is responsible for the loss of sexual appetite which is a very marked feature in these women, and how far it is consequent on the associated toxæmia, is a matter of question. In any case it is much influenced for good by the cessation of the auto-intoxication following on some satisfactory treatment of the defective intestinal drainage. It is not improbable that the more frequent presence of cystic change in the left breast results from the fact that the left ovary is damaged and rendered cystic very much more often than the right, owing to its fixation by or inclusion in the bands which obliterate the meso-sigmoid and shorten and straighten the sigmoid.

The pain due to movable kidneys, gall stones, gastric and duodenal ulcers, pancreatitis, renal conditions due to the narrowing of the right ureter by the band retaining the appendix or by suppurative about the appendix, uterine versions and flexions, and to many other conditions, which I believe are all effects of chronic intestinal stasis, are fairly characteristic.

It is difficult to separate abruptly the symptoms that are brought about mechanically from intestinal stasis from those which result from the consequent auto-intoxication, since many are due to both.

Here I would like to call attention particularly to the work of Dr. Victor Vaughan and Miss Wheeler *On the Effects of Egg White and its Split Products on Animals*, and of Dr. Török *On Experimental Studies on Round Ulcer of the Stomach and Duodenum*. I can do no more than refer to them here, but their importance in reference to intestinal stasis is obviously very great indeed.

The chief toxic symptoms are headache, a feeling of mental and physical lassitude, an inability to perform the ordinary duties of life, mental misery and distress, nerve symptoms as migraine, etc., which are comprised usually under the term of biliousness, and a want of control over the temper which renders these patients unhappy and unpleasant companions.

The symptoms for which the patient seeks relief at the hands of the surgeon vary materially with the position and occupation of the sufferer. While the unfortunate governess or domestic servant will struggle on until complete physical disability renders her incapable of performing her duties, the woman who has not to earn her

living calls attention rather to the mental distress from which she suffers. For this reason the patient in good circumstances receives attention at a much earlier stage in the disease than the poor worker, and either requires a less extensive operation, or benefits much more from a serious one. Too frequently the poorer patient has reached a stage in which operative procedures, however extensive, afford only temporary benefit, since the distension of the small intestine, having reached a certain limit, is liable to return and progress after an interval, and there is associated with this distension pain for which very little relief can be afforded.

Of the many cases of chronic intestinal stasis in private practice which called for operative interference, in nine only have I removed the large bowel. Of these one died, and that accidentally, from the bursting of a small deep-seated stitch abscess into the general cavity. Of the larger number of private cases in which division of the ileum and its junction with the large bowel was effected, there was no death from the operation. One of these patients died six months after the operation from acute obstruction. The cases in which simple division of constricting bands, or the establishment of a junction between the occluded ileum and the sigmoid or rectum, are sufficient are much more commonly met with in private than in hospital practice.

Auto-intoxication reduces the resisting power of the individual to the entry of organisms of various sorts and facilitates their obtaining a foothold in some of the tissues of the body. I will call attention to only one organism, the tubercle bacillus, since it illustrates very well this depreciation in the vitality of the tissues. The examination of a large number of dark-haired children affected with chronic tuberculous disease of joints will show the presence in them of unmistakable signs of auto-intoxication.

The examination of a number of girls suffering from lateral curvature or fixation of the asymmetrical position of rest will afford striking evidence of the effect of the toxin in depreciating the respiratory capacity and energy of the individual and will show them to be characteristically toxic. In them, as in the tuberculous cases alluded to, thoracic respiration is more or less completely in obedience.

TREATMENT.

If I have done nothing more than impress on you the importance of regarding chronic intestinal stasis as a very serious condition and one of which the capacity for harm is great and far-reaching in its results, I shall feel that my efforts have not been without result. We must acquire as thorough a knowledge as possible of the causation and pathology of delayed intestinal drainage and so endeavour to render our treatment of its several stages as scientific as possible.

I do not propose to discuss the medical treatment here, but will assume that the condition has developed to a degree that such treatment is obviously inefficacious to give the relief required. In other words, a stage has been reached in which owing to the delay in evacuating its contents the large bowel has not only ceased to perform a useful function, but has become such a source of danger that its removal from the drainage scheme will be of great service to the body.

It depends on the degree of development of the condition as to whether it is sufficient to separate and destroy constricting bands, or to divide the ileum and to connect it with the sigmoid or rectum, or whether it is necessary to remove the large bowel proximal to the junction. While in an early stage, and especially in the male subject, the obstruction at the hepatic or splenic flexures or at the sigmoid may be relieved by the division of bands producing constriction, in a late stage, when the small intestine has undergone extreme changes, the removal of the whole of the large bowel proximal to a junction between the small intestine and the sigmoid affords only a temporary alleviation of symptoms.

The most favourable cases for operation are those in which the symptoms are of a toxic rather than of a painful nature. In such the division of the ileum and its junction, with the lower part of the large bowel give complete relief to the symptoms and the consequent physical and mental improvement is extraordinary. When painful symptoms are much in evidence the large bowel should

be removed. The risk entailed by operation can be reduced very materially by first relieving the toxic symptoms by connecting the divided ileum with the sigmoid or rectum, and later, when the general condition of the patient has improved in consequence of this procedure, the large bowel can be excised if the symptoms demand it. I do not pretend that removal of the large bowel is not a very serious operation in certain circumstances. Indeed, in many of these patients any serious operation must be regarded as being dangerous to life, the danger varying chiefly with the degree of toxicity. I may say that in these and similar cases the risk can be very materially reduced by the subcutaneous injection of a large quantity of normal saline solution immediately before the operation. By this means the patient appears to suffer a minimum of shock from the extensive operative procedure, and vomiting either does not follow it, or should it do so, it is trivial in character. In these cases the absence of vomiting is a matter of very great importance. It was very frequent and severe after my earlier excisions of the large intestine, and was the cause of more than one fatal result. Besides the distress and depressing influence it exerted on the patient, the constantly recurring strain on a long wound was very liable to render it insecure or to determine the development of a septic infection in it, which would probably not have occurred had the recently incised structures been kept at rest. The risk of an infection starting in the peritoneal cavity appears to be very small. The mode in which the subcutaneous transfusion of normal saline, employed immediately before the operation, acts has been very clearly demonstrated by Dr. Crile's most interesting and valuable researches on the production of shock, of which America must be very justly proud.

HYPERTROPHIC OSTEO-ARTHRITIS OF HANDS WITHOUT VISCERAL OR CONSTITUTIONAL DISEASE.

By R. CARMICHAEL WORSLEY, M.R.C.S., L.R.C.P., COVENTRY.

J. L., the subject of the deformity illustrated by the accompanying photographs is a man, aged 47, one of a family of fifteen. One brother was born with two toes fused on one foot, the other foot normal. There is no history of any other abnormality in the family. The parents were not related in any way. The father was a very big, strong man, and is said to have been "double jointed" in the hands. He was a smith. J. L. was born with hands apparently natural, except that the middle finger of the right hand was crooked at the top joint. At 2 years of age this and the index finger of that hand, and the same two of the left hand, began to grow out of proportion to the general rate of growth, and the enlargement was most marked from the eighth to the fourteenth year of age. From the sixteenth year of age they have not hypertrophied further, but only taken part in the general growth.

The only movement now possible is at the metacarpophalangeal joint of the deformed fingers (the other fingers and thumbs having normal movement), all the other interphalangeal joints are ankylosed. At most of these joints (see photographs) there are large craggy nodosities, which feel cartilaginous, and over the dorsal surface of the

metacarpophalangeal joints of the first and second fingers of the left hand and middle one of the right are to be felt movable bodies, evidently cartilaginous, of $\frac{1}{2}$ in. to $\frac{3}{4}$ in. diameter, and one or two smaller pieces like "melon seed bodies." The enlarged fingers are transparent-looking at the more distal portions, and traversed by fine pink-coloured venules. The palms, especially the left, have huge pachydermatous pads, well seen in the photograph; the smaller pad next the thumb can be picked up, and has a thick, broad pedicle. The man generally carries his hands in his pockets. He is a boot finisher by trade, and says he can make a good living by it when work is plentiful. He has refused any operative interference.

BIOTRIPSIS, OR LIFE-WEAR: TROPHIC CHANGES IN OLD AGE.

[WITH SPECIAL PLATE.]

By G. LENTHAL CHEATLE, C.B., F.R.C.S.,

SURGEON TO KING'S COLLEGE HOSPITAL AND ITALIAN HOSPITAL.

THE appearance of the skin in an old person varies in different parts of the body. In this article I propose to call attention to the skin which has been subjected to the greatest exposure of the wear and tear of life. Dr. Head and Mr. Sherren have alluded to them¹; but, although I cannot find definite reference to them as a whole, there can be no doubt that the appearances are not described now for the first time. The changes in the greatly exposed skin are so marked that I think the general condition deserves a term to itself, and I propose "biotripsis" (life-wear), and to speak of a process of biotrophic changes. The condition is important from another point of view, for on the parts where it is most marked there is prone to occur papillomata and cancer.² Hence, if it could be shown that biotrophic changes are related to neurotrophic changes, the demonstration would support the two theories:

1. That a neurotrophic disturbance is concerned either directly or indirectly with the genesis of cancer.
2. That a neurotrophic influence bears upon the direction and limitation of the spread of cancer.

The biotrophic changes are observed most commonly upon the backs of the hands, the temples, and the foreheads of old people, but I have seen some of the changes upon the lower lips, cheeks, forearms, and occasionally elsewhere. The skin becomes shiny, smooth, thin, inelastic, pigmented, and apparently scarred, although the last cannot be explained by solutions of continuity of which there is no history.

The skin which shows the changes to best advantage is that which covers the second metacarpal bone and its immediate neighbourhood. The coloured plate which accompanies this article reproduces the most marked state in which I have seen this condition. It shows the backs of the hands of an old woman, aged 72. She did not complain of her hands, and had noticed nothing peculiar about them until she found I took an interest in them. She has never suffered from "chapped hands," nor has there been a solution of the skin's continuity. For the main part of her life she has been the wife of an agricultural labourer, and her duties have been domestic and household. I showed these hands to a distinguished

HYPERTROPHIC OSTEO-ARTHRITIS OF HANDS.

surgeon, and the first thing he did was to ask her, "How did you do this?"

The skin is shiny, smooth, inelastic. The subcutaneous

veins are almost subepithelial, there is a great degree of pigmentation, and there are in the most pigmented parts long radiating scars, which are more marked by loss of pigment than by the existence of cutaneous thickening. The condition is symmetrical; it is most marked in the region of the second metacarpal bone, and gradually fades away from this part. There is no similar change elsewhere on the hands. The tactile, heat and cold and pain sensations are not brisk, but it cannot be said that they are otherwise abnormal.

The condition very much resembles the bronzing of skin which has been subjected to prolonged exposure to the α rays. It is interesting here to remark that the two conditions are similar in another respect, namely, they are prone to be the seats of cancer.

It is difficult to account for biotriptic changes. In any country village in rural England many old people can be visited and the condition of their hands observed; it will be seen that they show great variety in the degree in which many of the biotriptic changes are present, although all their lives they have been exposed to prac-

Sir Victor Horsley has given me leave to publish a very interesting case which is under his care, and I take this opportunity of thanking him. The case bears upon the relation of nerve supply and pigmentation. Fig. 1 shows the head of a little boy whose right forehead is bald, the bone atrophied, and the skin pigmented in the region supplied by the supraorbital nerve of that side. Ten years ago he knocked the upper margin of the right bony orbit against the handle of a door.

It is a curious case from many points of view, and it makes one wonder that cutaneous pigmentation does not occur with greater frequency after operative and accidental traumatism. Whether pigmentation can be associated in any way with the cancer process is an undeveloped question. It is well known that pigmented cancer is a highly malignant type of cancer. Does the presence of the pigment in the malignant epithelial cells mean that they possess great resistance and vitality?

It appears from P. Carnot's experiment that the normal pigmented epithelial cells of variegated guinea-pigs possess greater vitality or resisting power than their white epi-

FIG. 1.

FIG. 2.

tically the same wear and tear of life. Hence the same wear and tear of life can induce in different skins different degrees of the biotriptic changes.

Skin which has been deprived of its nerve supply becomes smooth, shiny, inelastic, and atrophied, and in herpes zoster it is scarred. With regard to the relation between pigmentation and nerve supply there is much evidence to show that it may be close. But from the evidence at our disposal we cannot state definitely whether disturbance of nerve supply (1) induces an intracellular manufacture of pigment, (2) or whether it induces changes in the blood vessel walls which allow diapedesis of red blood corpuscles, the pigment of which is deposited either outside the cells of the part, or even picked up by them and incorporated within them.

Anaesthetic leprosy, Addison's disease, melanoderma, leucoderma, moles, and the greyness of hair seen in the heads of people "turning grey" all indicate by their distribution or associated nerve lesions a possible connexion between pigmentation and nervous influences.

The action of the nervous system upon normal pigment is shown in Lord Lister's classical experiment¹ in which he demonstrated that the change in colour of frogs when taken from the light into the dark and vice versa depends upon a reflex the afferent fibres of which traverse the optic nerves.

thelial cells when both kinds are grafted on to the same raw surfaces. There is at present no evidence to show that cancer is more frequent in negroes than in white races, nor can one say that the skin of brunettes is more liable to cancer than that of blondes, nor is cancer known to be more common on the most pigmented parts of the skin of any person, black or white.

Dr. Ironside Bruce has kindly sent me a case which bears upon this point. The patient is a woman, aged 60, and Fig. 2 shows that there is a rodent ulcer upon the internal extremity of the lower eyelid on the right side. The skin around the lower eyelid had become highly pigmented, especially at the point on which the rodent ulcer began, and some pigment also exists in a minor degree on the other side of the nose. This pigmentation had occurred some years before the appearance of the rodent ulcer.

Dr. Ironside Bruce's case is an example of what I mean, but it may be an exception to the rule, and more evidence is wanted on this point.

SOME ASPECTS OF THE LEGAL RESPONSIBILITY OF MEDICAL MEN.*

BY

A. DOUGLAS COWBURN, M.R.C.S.ENG., D.P.H.LOND.,
OF THE MIDDLE TEMPLE, BARRISTER-AT-LAW.

HISTORICAL.

From the earliest times of which we have any authentic records, the responsibilities, liabilities, and privileges of medical men have been the subject of legislation. Yet the measure of that responsibility has varied greatly in times past, and amongst divers nations. The oldest known Code of Laws, promulgated by Hammurabi, King of Babylon, during the period 2285-2242 B.C., and which is believed by scholars of Assyriology to embody the best judicial decisions prior to that period, enacted the privileges, fees, and serious liabilities of those venturosome enough to practise medicine and surgery. After laying down a scale of fees which then, as now, varied with the social status of the patient, the code proceeds:

If the doctor has treated a gentleman for a severe wound with a lancet of bronze, and has caused the gentleman to die, or has opened an abscess of the eye for a gentleman with a bronze lancet, and has caused the loss of the gentleman's eye, one shall cut off his hands.

If a doctor has treated the severe wound of a slave of a poor man, and has caused his death, he shall render slave for slave. If he has opened his abscess with a bronze lancet, and has made him lose his eye, he shall pay money, half his price.

In later times, when priests assumed the function of medical practitioners and performed surgical operations, they enjoyed almost complete immunity as far as legal liability was concerned, for their knowledge, being supposed to be of a divine origin, was looked upon as infallible. On the other hand, among the ancient Egyptians the surgeon who ventured beyond the boundaries of the rules then in vogue, was liable to suffer corporal punishment even though the practice was successful. Among the western Goths the unsuccessful ministrations of the surgeon, if resulting in death, were followed by his being handed over to the vengeance of the relations of the deceased.

CRIMINAL LIABILITY OF THE MEDICAL PRACTITIONER.

The motives actuating every medical man must be to heal, to relieve suffering, and to prolong life. If he intentionally use any means to shorten life he is guilty of murder, and since the law imputes to any person the intention of bringing about that which is the obvious consequence of any wilful act, if he use any means, knowing that the inevitable resultant consequence thereof will be the shortening of life, he is guilty of murder. Moreover, although any person (whether qualified or not) who professes by way of occupation to deal with the life or health of His Majesty's subjects is bound to possess competent skill to perform the task that he holds himself out to perform, and is also under a duty to treat his patients with care, attention, and assiduity (*R. v. Spiller*, 1832, 5 C. and P. 333), these correlative duties are even more emphatically binding upon duly qualified and registered medical practitioners than upon others (*R. v. Crook*, indictment for manslaughter, 1859).

It is culpable negligence for a practitioner to omit giving either to the patient or to the person immediately in charge thereof, necessary directions as to the use of a dangerous drug, substance, or thing (*R. v. Chamberlain*, 1867, 10 Cox, C.C. 466).

It is, however, admissible evidence for a defence on a trial for manslaughter of a patient to show the remedial effects upon other persons of the particular means which caused the death of the person in question (*R. v. Long*, 1830, 4 C. and P., 398-423); but even if the remedial measures employed were the actual cause of death, or if the death was in any sense accidental or due to an honest mistake on the part of the practitioner, or if the fatal result was one which even with skill he could not reasonably have foreseen, he is not guilty of any offence, and the court will discourage a conviction where a practitioner has, with the bona-fide intention of healing, exercised his best skill, as in the case of *R. v. Van Butchel*, where the prisoner passed a rectal bougie on the deceased, who had

a disease of the rectum. The instrument on being inserted caused great pain, and shortly after the patient died. *Post mortem* the rectum was found to have been perforated. The judge considered that this case did not even approach to manslaughter, and directed an acquittal.

It is improbable that any but very serious cases of malpraxis would be dealt with as crime at the present day, although, as a matter of strict law, even a technical assault, such as vaccinating without consent or examination against a patient's will, is a crime as well as a tort. To the honour of the profession, it may be added that such cases are of the rarest possible occurrence, and when they do occur juries are not eager to convict, except where they think that prisoner has shown culpable ignorance or inattention or rashness under all the circumstances of the case.

CIVIL LIABILITY OF THE MEDICAL PRACTITIONER.

In all cases of skilled or professional labour, where a man publicly practises a profession, he holds himself out as being properly equipped for its due performance. He represents and undertakes, therefore, that he is possessed of the necessary and customary skill pertaining to that profession (*Harmer v. Cornelius*, 28, L.J.C.P., 85). He does not, if an attorney, undertake that at all events you shall gain your case, nor does a surgeon undertake that he will perform a cure, nor does he undertake to use the highest degree of skill. There may be persons who have a higher education and greater advantages than he has, but he undertakes to bring to bear a fair, reasonable, and competent degree of skill (*Lamphier v. Phipps*, 8 C. and P., 479). Whether the practitioner be qualified or unqualified matters nothing. The legal wrong is the incompetent or negligent treatment, not treatment by one wanting a qualification. The qualified man is an expert, the unqualified man has put himself into the position of an expert, although in the case of one who did not assume to be a medical practitioner evidence of gross ignorance would be required to render him liable to damages in a civil court, whereas in the case of a regular practitioner the ratio would be such reasonable knowledge and skill as is usual among medical men.

The degree of skill requisite is such as may be expected in the circumstances of time and place from an average person in the profession, one neither specially gifted nor extraordinarily dull, and where the reasonable amount of skill proportioned to the duties that are undertaken is found, there is no liability for error of judgement in the application of knowledge. Each case depends upon its own circumstances, and where an injury has been sustained that could not have arisen except from the absence of reasonable skill, then there is liability (*Hart v. Frame*, 6 C. and F. 193). Nevertheless the standard of care and competence is variable, for example, that might be negligence in a doctor of repute who holds a recognized position on a hospital staff, which would not be so in the case of a village doctor in the wilds of Kerry. What constitutes a reasonable degree of skill cannot be defined. It is a question of fact to be determined by the jury in the light of the circumstances of each case.

Treatment involving probabilities of danger cannot be applied without communication to, and some expression of consent by, the patient, although the duty to forewarn the patient is discharged by a general intimation of likelihood of pain or danger without going into a scientific dissertation on the probabilities and peculiarities of the case.

A medical man is usually responsible for the torts of his apprentice or assistant if the act complained of be done under his directions, with his authority, and in the particular manner sanctioned by him, but not otherwise. Nor are doctors in a hospital responsible for the negligence of the nurses therein unless they are in close proximity to the patient at the time of the commission of the wrongful act, and consequently able to prevent it. If it be not the usual hospital practice for them to superintend every minor detail, a patient who goes there cannot complain if they omit to do so in his case.

Speaking generally, no one can be held responsible for another's negligence unless the relationship of master and servant or of principal and agent exists. Hence a qualified assistant or locum tenens is himself responsible for any negligence proved against him. He does not involve his

* From a paper read before the Medico-Legal Society

principal unless the principal has employed him, knowing him to be incapable though qualified. And where, in a recent case, the plaintiff, a qualified medical man, sought to make the defendants, the governors of a hospital, liable for alleged negligence in conducting an operation upon him at the hospital, resulting in injury to his arm by burning and pressure while he was under the influence of an anaesthetic. It was held that the relationship of master and servant between the hospital staff and the governing body of the hospital did not exist, that if there was negligence, the operating surgeon who had control of the proceedings would be liable, but that the governors of the hospital were not liable for the negligence of the staff even if proved.

RELATIVE RESPONSIBILITY OF THE SURGEON AND ANAESTHETIST.

There does not appear to be any recorded case in England in which either criminal proceedings for culpable negligence or a successful civil action has been brought against a medical man on account of a death resulting from or occurring whilst under the influence of a general anaesthetic, which is probably the reason why no authoritative ruling laying down the exact degree of responsibility attaching to the operator and the anaesthetist respectively has ever been given. In all probability each case would be left to the jury to be decided in the light of the particular circumstances, but as the question has been the subject of much recent discussion the following observations, though unsupported by direct authority, are submitted for consideration.

It is well understood in the profession that the administration of an anaesthetic is a grave and responsible duty requiring undivided attention and unremitting vigilance on the part of the administrator, who, as such, has nothing to do with the operation *per se*, except in so far as it affects the administration. If negligence be proved in respect of such administration, the medical practitioner actually administering the anaesthetic is liable, not the surgeon who is engaged in the operation. But if the surgeon take upon himself to decide the particular kind of anaesthetic to be employed, or the apparatus to be used, or the amount of anaesthetic to be administered, he would probably be held jointly responsible with the anaesthetist for any unfortunate result to the patient—assuming negligence to be proved. Liability as against the administrator might arise from omitting the duty of careful physical examination, of previous appropriate preparation, or from leaving the patient before the administrator has had reasonable grounds for assuring himself that the case could be so left in safety.

Liability, it is apprehended, might also arise from committing the irregularity of assisting the surgeon while engaged in the administration of the anaesthetic (urgent necessity excepted).

But where a nurse or student is engaged in the administration of an anaesthetic under the direct supervision of a medical man, there (it is apprehended) the relationship of master and servant exists, the nurse or student being under the direct control of the medical man as to method, quantity, and kind of anaesthetic employed; hence the qualified man is responsible. Where circumstances compel an operator to accept the services of an unskilled or non-professional person, the operator must take the entire responsibility of the administration.

It is customary, though not the invariable practice, for the surgeon to select the anaesthetist, and generally control the procedure of the operation. If an operating surgeon can be properly charged with selecting an anaesthetist who has not had sufficient experience to enable him to give the anaesthetic properly, in case of a fatal result the surgeon might be held liable.

But apart from gross negligence, which is probably of the rarest occurrence, it is submitted that attempts to make medical practitioners liable to legal consequences for deaths occurring while an anaesthetic is being administered would damage humanity at large.

Moreover, where pure anaesthetics are administered, it would be difficult, in view of the fact that differences of opinion exist as to the exact manner in which anaesthetics act, to state the precise mechanism of the fatal issue, and hence the extent of the responsibility of the administrator.

CONSENT.

The law extends its protection to all, not only against actual hurt and violence, but against every kind of bodily interference and restraint not justified or excused by allowed cause; and, speaking generally, and apart from certain statutory requirements under the Workmen's Compensation Acts, a medical practitioner has no right to treat in any way, or even examine another, without his consent (persons in the public service and convicted prisoners excepted); and, should he do so, this technically amounts to an assault, which may give rise either to criminal proceedings, or to a civil action for damages. Even in cases where the patient actually consents, if such consent is obtained by fraud on the part of the practitioner he is guilty of assault—for example, if a parturient woman consented to be attended in childbirth by a medical practitioner because she relied on his fraudulent statement that he had not been lately attending any cases of scarlet fever, his attendance on her under such circumstances would amount to an assault.

Nevertheless, there are also circumstances in which a man's person may have to be dealt with promptly for his own obvious good, but his consent, or the consent of anyone having lawful authority over him, cannot be obtained in time. And it is not an assault for a competent surgeon if he perceives that an operation ought forthwith to be performed to save life to perform it without consent, such being a work of charity and necessity.

Generally speaking, it is implied that the practitioner shall, so long as the relationship of doctor and patient exists, do all that is necessary in his opinion for the welfare of his patient, within his province, subject to the proviso that when a dangerous or extensive medical or surgical proceeding is contemplated, the patient ought to be warned of the possible consequences, and given an opportunity of declining to undergo the treatment proposed.

Where a practitioner is requested by a mistress to examine a servant who is believed to be pregnant, it is highly important to obtain the consent of the servant both to the examination and to the making known to the mistress the information gained thereby.

The great importance of obtaining consent to such surgical proceedings as may be found necessary is obvious in these days when "explorations" may reveal a state of things requiring subsequently prolonged and extensive surgical proceedings.

The law of England in its relation to medical men is not, as is too commonly supposed, a professional mystery, nor is it a collection of decisions which "squint both ways."

Though possibly uncertain in some few particulars and incomplete in others, yet, viewed as a whole, it takes full, and even generous, cognizance of the anxieties and difficulties inseparable from medical practice, and in its dealings with medicine, as with other arduous and honourable callings, it embodies those notions of fair play, justice, and humanity by which Englishmen are governed in their public and private affairs.

NOTES ON A THIRTY DAYS' FAST.

By F. PENNY, M.R.C.S.,
...LOPEN, ILMINSTER, SOMERSET.

THESE notes are from personal experience of myself, a medical man, aged 46, height 5 ft. 7 in., whose weight for years prior to 1905 had averaged 11 st. 3 lb. net. Since that date I have been a purin-free vegetarian, and have dropped about 10 to 14 lb. in weight.

I felt, and was considered to be, in fairly good condition, but I undertook this fast to endeavour to satisfy myself whether the accumulation of waste and unnecessary material in the system is the real cause of much disease, and whether a prolonged fast is a sound method of elimination and as such conducive to bettered health.

Most of my observations are tabulated, the measurements, weights, blood counts, etc., being checked by another medical man. The morning records were taken in bed about 9 a.m., and those of the evening between 10 and 11 p.m., before retiring. The respiratory count, being my own, may unconsciously have been modified for the occasion. The spirometer records were taken by a Lowne's spirometer, and, though relatively correct, I

* Weight after drinking 4 pints.

consider them absurdly high, in spite of authoritative statements that the instrument gives correct readings. My respiratory capacity on a von Brockmann's spirometer was before the fast 275 cub. in. and after its completion 255 cub. in.

My drink consisted of distilled water only, except that on the sixteenth day I added a little salt; on that day, as an experiment, I drank 8 pints.

Blood Counts taken on the Twelfth, Twentieth, and Thirtieth Days.

	Red Corpuscles.	White.	Poly-nuclears.	Large Mono-nuclears.	Lymphocytes.	Eosinophiles.
			Per Cent. 76	Per Cent. 12	Per Cent. 12	Per Cent. —
Twelfth day	6,600,000	10,000	76	13	6	—
Twentieth day	7,000,000	11,000	76	13	6	—
Thirtieth day	6,000,000	8,800	70	20	7.5	1.5

200 corpuscles were counted on each occasion.

Haemoglobin varied from 104 to 112 per cent.

Blood pressure (taken by a Martin's modification of the Riva-Rocci sphygmomanometer) fell steadily during the fast from 110 to 90½ mm.

Measurements.

	Before.	After.
	Inches.	Inches.

Chest contracted ...	34½	31½
Abdomen ...	31	26½
Hips ...	35½	32½
Thigh ...	21	18
Calf ...	15½	12½
Ankle ...	8½	7½
Arm ...	13	11½
Forearm ...	11½	10½
Wrist ...	6½	6½

My urine remained acid and clear until the twenty-second day, after which there were copious deposits of "uric acid crystals" and also of "urates." I had been subject to bouts of this sort for years whilst on a mixed

diet, but I shall be glad of the explanation of such an occurrence after a twenty-two days' fast. The bowels acted only after enemata, eight plain water ones being given. Three Turkish baths were taken to assist elimination.

My time was occupied chiefly in reading, exercise, and conversation. I retired generally between 10 and 11 p.m., and generally spent twelve to fourteen hours in bed with the windows wide open. My average loss of weight was 1 lb. a day. My exercise was walking three miles and a half and cycling five miles and one-fifth a day. After the first two days I felt no hunger. I suffered much from cold, especially in the feet and hands, probably to some extent due to my being too lightly clothed for this climate. At times I was very irritable. Throughout the fast my tongue was coated and my breath offensive. During the last eight days I had very little inclination for exertion of any kind.

This fast was broken on the completion of thirty days with 1 lb. of fruit, in spite of eating which my weight dropped 1 lb. during the next seventeen hours, and my urine was loaded with "urates." Then I took fuller meals of milk, rice, fruit, toast, honey, etc., and gained weight rapidly ($\frac{1}{4}$ lb. in two days). I then had some travelling to get through, and on the third day took a long railway journey, including crossing London; on the fourth day I cycled fifteen miles, and took another long railway journey, and during the following night I had acute dyspepsia with very violent diarrhoea, which latter continued, with intermissions, for three days. After this I ate well and steadily, gained weight (10 lb. in ten days). During the third week my mouth was very tender, and my sublingual glands were considerably swollen, and during this week I gained 3 lb. in weight.

For some days during the second and third weeks there was very free diuresis.

This fast was not carried to a finish—that is, until my tongue cleaned and natural hunger returned, as described by Dr. Dewey—and I have not yet completely satisfied myself with regard to the objects for which the fast was undertaken, but I hope for better success next time.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

A CASE OF TRUE ELEPHANTIASIS.

The unfortunate young Zulu shown in the photograph was committed to gaol for a breach of the peace; his age is from 22 to 25; he is pleasant and intelligent and in good health, with the exception of the condition of his foot and leg. He was, he says, in a normal state of health up to 8 or 9 years of age, when the trouble commenced in his foot, and has gone on to its present state. He tells me that he is the only member of his family with this affection, and he has not heard of any ancestor being so troubled. He has a little pain at intervals, but, as a rule, beyond the weight and unwieldy condition, he is not troubled. I find there are two or three similar cases in this district, which is a small percentage, considering that there are about 30,000 natives in the Mapumulo division. Unfortunately I did not get a lateral picture, which would have shown more folds of hide-like skin so characteristic of the elephant.

H. S. REYNOLDS, F.R.C.S.E.,
District Surgeon, Mapumulo, Natal, S.A.

NAEVUS PIGMENTOSUS.

The accompanying illustration shows an Armenian child, aged 2, who was seen by me in Ispahan, Persia. She was being taken to India to be exhibited. She is a bright, intelligent girl, rather fairer than is usual among children here. Large hairy moles cover a large portion of her body. There are considerably over 100 in all. The largest is on the left side, extending from the region of the left scapula behind to about 2 in. to the right of the umbilicus in front. In its widest part it measures $\frac{1}{2}$ 12 in., breadth 7 in., diagonally 17 in. There is a patch 5 in. by 4 in. on the right buttock. There is one tuft of hair above the left eyebrow, otherwise the face is normal. There are several moles on the scalp. Both labia have an outgrowth of hair on them. The moles on the legs are more pedunculated in character. The hair on the moles is about $\frac{1}{2}$ 1 in. long and darker than that on the head. It is very fine.

The patient is the third of a family of four children. There is no hereditary history of naevus pigmentosus, nor of maternal impression.

ELIZ. N. MACBEAN ROSS, M.B., Ch.B. Glasg.

KENSINGTON INFIRMARY.

EPITHELIOMA OF OESOPHAGUS IN A WOMAN AGED 26.

(By J. BASIL COOK, M.D., D.P.H., Senior Assistant Medical Officer.)

M. C., aged 26, was admitted on April 23rd, 1909, and died two days afterwards.

History.

She had been losing flesh for three months, and for the past seven weeks had experienced considerable difficulty in swallowing. There was no family history of cancer.

Condition on Admission.

She appeared very ill, was emaciated, and was quite unable to swallow solid food, and liquids only with difficulty. There was no coughing or regurgitation after swallowing, but she groaned both when awake and asleep. No history could be obtained of her having swallowed any hot or corrosive fluid; there was no evidence of syphilis, nor any sign of thoracic growth, aneurysm, or pharyngeal abscess. The heart and lungs were normal. There was some obstruction of the air passages as there was marked recession on inspiration. At the level of the cricoid cartilage there was a slight fullness of the throat, and about 2 in. lower down on the right side a small, hard gland was easily palpable. There was an offensive blood-stained discharge from the throat. An unsuccessful attempt was made to pass various sized bougies, which when withdrawn were bloodstained. The obstruction was opposite the cricoid cartilage. The patient was fed with nutrient enemata.

Post mortem there was an epitheliomatous growth completely surrounding the upper end of the oesophagus, and extending downwards for a distance of 4 in. Beyond the small gland in the right side of the neck there was no sign of secondary deposit anywhere. The thorax and the organs of the body were free. The tonsils were apparently healthy.

REMARKS.

This case is chiefly interesting on account of the rarity of the condition in so young an individual. Gastrostomy was contraindicated because of the grave condition of the patient. The offensive discharge and obstruction to the passage of a bougie enabled one to diagnose the case and to eliminate the hysterical dysphagia occasionally met with in young women.

SECTION OF MEDICINE.

Friday, May 14th, 1909.

W. G. SMITH, President, in the Chair.

Clinical Evening.

DRS. O'CARROLL and PURSER exhibited a case of *Progressive Bulbar paralysis* in a man 56 years of age. A year ago the patient first noticed a certain amount of difficulty in his speech. It was very indistinct, but still intelligible. He was now hardly able to protrude the tongue beyond the lips. He had a little difficulty in getting food back, but he did not complain of difficulty in swallowing, except occasionally with liquids. He complained of difficulty in holding his head up. There was a little wasting of the muscles of the thumb, and of the biceps and triceps of the right side. The knee-jerks of each side were sharp, and occasionally, on stroking the sole of the left foot, Babinski's sign was found. They also exhibited a case which had been diagnosed as locomotor ataxy. The patient was a young man, 25 years of age, married at 19, the father of two healthy children. There had been no miscarriages. There was a distinct history of congenital lues. About a year ago he got suddenly weak in his left leg, with a pain in his knee. Since then he had had a progressive difficulty in walking. Some two years previously he had "seen double" for a short time. His present condition was that he had not got paralysis of any muscles, but had considerable difficulty in walking, and was very ataxic. Absence of knee-jerks. The pupils contracted neither to accommodation nor light. He appeared to have no loss of sensation in the limbs, but was rather slow in recognizing touches on the left leg, especially from the knee down. He had a certain amount of difficulty in passing water; he often had to press, and sometimes it came away without sufficient warning. He had always been a little deaf. Dr. DUFFY exhibited (1) two cases of *Hereditary ataxia*—sisters, aged 11 and 13—in whom the disease had been noticed about three and five years respectively. The younger was the much more advanced case. She stood fairly well with the feet apart, but could not balance at all with her eyes closed. The elder girl had sometimes a slight shaking of the hand, which was only noticeable when watching closely. There was no sensory disturbance, or disturbance of the sphincters. The eye symptoms were variable. In the younger girl there was slight nystagmus, but some days it was absent altogether. In both cases there was a total loss of knee-jerks. The limbs were well nourished. The younger girl showed well-marked lateral curvature, and both feet were getting flat. She had a systolic murmur heard near the apex, and at the base of the heart she had a loud systolic murmur when lying down, which disappeared when she sat up. The day following the observation of the latter murmur it was exactly the reverse—that is, it was absent when lying down and present when erect; it varied from day to day. Her sister had the same. When they came to hospital they were very thin, but they had grown fatter and better in colour after a couple of months on arsenic. (2) A case of *Idiopathic muscular atrophy* in a young man, aged 24. The patient had not noticed anything peculiar about his condition, except that he knew he was not a very powerful person. There was great thinness and want of muscle everywhere. There was no actual atrophy, but he took it that it was still in an early stage. Such cases were usually met with in groups, but there was no history of such in the present case. Although they could not find anything in the way of thoracic disease, still he had extremely marked myoidema. His grasp was feeble, but he had quite well-marked knee-jerks. Dr. T. G. MOORHEAD read a paper on *Grocco's triangle*, giving his observations on the subject for some years past. Dr. KIRKPATRICK said he had looked for the sign during the past two years, and had endeavoured to demonstrate it. He could sometimes demonstrate it to his own satisfaction, but he had often failed to do so to others looking on. It was in cases of small effusion that the sign was of particular value, and it was in such cases that it was very difficult to elicit it. The

PRESIDENT said that, short of *post-mortem* evidence, some mystification hung over the subject. It took 10 oz. of fluid to produce recognizable physical signs, and in cases of large effusion the sign was hardly necessary. Dr. MOORHEAD, in reply, said he was an advocate of early removal of fluid, and endeavoured to demonstrate it. In three of the five cases in which he did not get the sign he also demonstrated fluid, but he had not been able to demonstrate the relationship between the size of the triangle and the effusion. Dr. PEACOCK recorded a case of glioma of the spinal cord in a girl, aged 11.

Reviews.

FRACTURES AND SPRAINS.

SIR WILLIAM BENNETT is the first and chief exponent in this country of the doctrines of Dr. Lucas-Championnière. We welcome the appearance of a fourth edition of his *Lectures on Massage and Early Movement in Fractures*,¹ as evidence of a steadily growing interest in the subject on the part of the medical public. The main part of the book differs little from the third edition, published six years ago, but the number of illustrations is increased, and a chapter on sprains and their consequences, and one on stiffness of the spine, take the place of one on derangements of the knee-joint, which appeared in the earlier editions. There is therefore little to be said of the first two lectures, which have been noticed in former reviews of the book, but on comparing it with Dr. Lucas-Championnière's *Traitement des Fractures par le Massage et la Mobilization*, which was published in 1895, it will be noticed that Sir W. Bennett appears to attach more importance to reduction of fractures, and uses apparatus more than does the originator of the method. Despite this, however, his treatment is essentially the same, in that the apparatus is not applied tightly, and that it is soon and often removed for massage and passive and active movement. The lecture on sprains has already appeared in our pages (December 8th, 1906), and that on stiffness of the spine has also been published before, so that it is not necessary to say much about them on this occasion. The first contains useful hints on the treatment of sprains on the same principles as for fractures; in which latter category the x rays have shown that many supposed sprains should be included. In the second lecture the various causes of stiffness are detailed, and the diagnostic value of the symptoms discussed.

Dr. WHITELOCKE has had rather exceptional opportunities of studying sprains and allied injuries of joints² in young adults, owing to his position as surgeon to the Radcliffe Infirmary and Lecturer on Surgery at Oxford, where a large number of young men occupy themselves with athletic pursuits, which render them liable to injuries of many kinds. This book deals with many so-called minor injuries, some of which are little understood by the majority of surgeons, and which too often fall into the hands of bonesetters, with results lamentable for the patient, while the few striking cures, which serve only too well to advertise the "professor," are due more to good luck than skill. The scope of this work is wider than its title might lead some to suppose, for it includes many fractures of and in the neighbourhood of joints, as well as sprains and strains of muscles and ligaments. The treatment of internal derangement of the knee-joint and of ankylosis are also included. The author is at one with Dr. Lucas-Championnière in that he relies little upon apparatus, but his experience of massage and early movement in the treatment of fractures and injuries of joints appears to have led him to conclusions very different to those of the distinguished French surgeon. Possibly the difference of opinion is due to Dr. Whitelocke having had to deal mainly with young subjects, and his views are not so directly opposed to those of Dr. Lucas-Championnière as at first sight appears. For the latter has expressly stated that early massage of fractures is not advisable in the case

¹ *Lectures on the Care of Fractures and Early Movement in Fractures*. By Sir William H. Bennett, K.C.V.O., F.R.C.S. Fourth edition. London: Longmans, Green, and Co. 1899. (Demy 8vo, pp. 144, with 25 illustrations. 6s.)

² *Sprains and Allied Injuries of Joints*. By R. H. Ansell Whitelocke, M.D., M.C., F.R.C.S. Oxford Medical Publications. London: Henry Frowde, and Hodder and Stoughton, 1909. (Demy 8vo, pp. 221. 7s. 6d.)

of children, in whom it is apt to produce too exuberant callus; and this tendency to too abundant exudation may continue for as long as the growth of the cartilages persist. Certainly the most striking results of the early massage and movement treatment are to be seen in older patients, who were too often disabled after treatment by prolonged fixation. The author records three cases of fracture of the scaphoid bone of the wrist, in two of which the diagnosis by *x* rays was not made till late, while in the third it was made directly after the injury. Consequently, the two first were treated by massage and movement, while the third was treated by rest. The disability and pain in the first two cases were indefinitely prolonged, while the third patient was as well as ever in six weeks. If we may argue from so small a number of cases, the author's conclusion that in this particular injury rest is the proper treatment, is irresistible. An even more important lesson to be derived from them is the necessity of radiography in the diagnosis of what may seem to be mere sprains of the wrist, and, we may add, of sprains of the fingers also. The descriptions of various unusual sprains and displacements of tendons should be very useful, for these not very common and not very serious injuries are scarcely treated of at all in the formal textbooks of surgery: yet in no cases more than in these does the surgeon stand to gain or lose reputation according as his diagnosis and treatment are right or wrong. We would enter a protest against the recommendation of proprietary preparations, when the same therapeutic effect can be attained without them. This book is well illustrated and printed, like the rest of the series of Oxford medical publications, and it will no doubt have a large sphere of usefulness.

DRUGS AND THE DRUG HABIT.

Of the many books that have been written about drugs it can be said of very few that they possess much interest beyond that concerned with the dry, hard facts with which they deal. Even the still more numerous books which treat of drugs in their therapeutic application seldom arouse any sense of satisfaction from either the literary or philosophic point of view.

A volume recently published by Dr. HARRINGTON SAINSBURY, entitled *Drugs and the Drug Habit*,^{*} is a notable exception to this general rule. In his preface, Dr. Sainsbury states that his treatise has for its main object "to look at the essentials of the task which disease sets and drugs undertake, and to discuss with what show of reasonableness the medicaments can claim to be equal to their task." To accomplish his purpose the author wisely avoids multiplicity of details, and by dealing with general principles he presents his readers with a clear and comprehensive view of the position which drugs ought to occupy in their relation to the prevention and treatment of disease, of their influence upon the human mind as well as the body, of the necessity for their adaptation to personal requirements and idiosyncrasy, and finally of their possibilities for evil when allowed to pass from the sphere of use to that of excess.

The first chapter is devoted to an interesting and instructive review of the history of medicine from the earliest mythical times of the immortal gods, down through the days of Aesculapius, Hippocrates, Celsus, Dioscorides, Galen, Paracelsus, Harvey, and Sydenham, to the more recent times of Pasteur, Koch, and Lister. The author then proceeds to develop his subject by pointing out that the objective of drugs is the cure of disease and that therefore, from the widest standpoint, the term "drug" comprises not only the *materia medica* of the *Pharmacopoeia*, together with all the more recent serums, vaccines, antitoxins, and organic extracts, but also the psychic effects of hypnotism, and all the various systems of "faith cures." The value of suggestion as an aid to recovery from disease is undoubted, and, consciously or unconsciously, it plays its part in every curative process that is undertaken. As to the ethics of its deliberate employment, Dr. Sainsbury says: "It is a power and it should be used; it is a power and it may be abused; it is there for the honest physician, and it is there also for the charlatan." Unfortunately, it is the weapon

against disease which the quack finds most suitable to his methods, and so it is, of all others, that which has been most unscrupulously wielded in the treatment of those who are over-credulous and who, in the feebleness of their individuality, refuse to accept pain as a necessity of human existence, and spend their lives in an insensate attempt to escape, at all costs, every form of discomfort.

But pain drives all men, sooner or later, to seek relief from its tortures, and is mainly responsible for the tyranny of sedative drugs as well as for the popularity of secret quack remedies, and of Christian Science, Faith Healing, and every other fashionable craze which poses as a panacea. Although persistent pain, whether of mind or of body, may provoke the abuse of narcotic drugs, their proper use ought not to be discouraged: the one essential is what Dr. Sainsbury calls their *controlled* administration. When anodynes are thus employed,

drug treatment, instead of degrading the moral sense, may actually become a means of building it up: for the patient who accepts the restrictions as to the use of the palliative, and is willing to bear himself resignedly until the time appointed for relief, is actually submitting to a form of discipline which may tax to the uttermost his powers of endurance, and which if endured cannot fail to strengthen his moral fibre.

Without the saving grace of control, the risk from the continued use of all drugs, but especially of those which are sedative or stimulating in their effect, is the creation of a habit, and one of the most pernicious characteristics of the drug habit is the need which it engenders for increasing dosage. It is pointed out by Dr. Sainsbury that the persistent administration of a drug under certain circumstances—as, for instance, in the case of such a disease as myxoedema—is a beneficent habit; but habit becomes injurious when it is created and indulged under such conditions as to render its relation to the welfare of the economy evil. He says: *2801 ON 6741 01 101599 01 01*

To regard the question of habit and control alike, now when Life touches its zenith, and now when it is within sight of harbour, is not to follow the dictates of reason. Sometimes in the midst of seeming health, in the full tide of things, the warning comes that we must make ready for departure, as when a cancer declares itself: and not to take into account this new fact and make due allowance is to prove ourselves unskillful mariners. Habit is not to be made into a bogey, neither is control to be made into a fetish. Life always will run betwixt its Scylla and Charybdis: it is meant so to run; that is why the helm is put into our hands to guide. It is meant that we should have the opportunities to show ourselves courageous and prudent steersmen, but these opportunities the great waters only can give. If for fear of establishing a habit through misuse we forego the benefits which are here to our hand for use, we shall inevitably limit the scope of life, and so narrow its outlook and cramp its purpose.

In a chapter devoted to the uncontrolled habit, detailed consideration is given to the leading sedative and stimulant drugs which furnish the most striking examples of habituation, and especially to opium and its derivatives, and to alcohol. The author's views will well repay the careful attention of all who devote attention to the great sociological problems which have arisen out of the widespread custom of careless recourse to, as well as out of the unhappy prevalence of excessive addiction to, these potent and popular indulgences.

Passing finally to the question of prevention and cure as they apply to injurious drug habits, Dr. Sainsbury contends that there is need for greater regard to the new science of eugenics, for the more careful education of the child both by precept and example, and for the assistance of the State to secure a proper quality of food and a standard purity of medicine, and of such other articles of daily consumption as tea, coffee, and alcohol. As regards alcohol, a wise word of warning is given to the extremist when he is reminded "that temperance promises a higher moral yield than total abstinence; that the aim of all education should be to develop character, to create a people strong willed for good; that it is possible to pay too high a price for sobriety, and that this excessive price is paid when liberty of action is forfeited."

Enough has been said to indicate the scope and merit of Dr. Harrington Sainsbury's book. We congratulate him upon the production of a treatise which for breadth of view, temperance of exposition, simplicity and clearness of style, deserves to be carefully read, not only by members of his own profession, but by all to whom the public weal and the betterment of the race are questions of interest.

^{*} *Drugs and the Drug Habit*. By Harrington Sainsbury, M.D., F.R.C.P., Senior Physician to the Royal Free Hospital; Consulting Physician to the City of London Hospital for Diseases of the Chest (The New Library of Medicine). London: Methuen and Co. 1909. Demy 8vo, pp. 321; illustrations 11, 7s. 6d.

OBSTETRICS.

We noticed the second section of the *Edinburgh Stereoscopic Atlas of Obstetrics*⁴ in our issue for August 29th of last year. The third section consists of twenty-five further stereoscopic photographs, illustrating the delivery of the child and placenta, the application of forceps, the diameters of the fetal head, and Walcher's position. The student who uses these diagrams has at least the satisfaction of knowing that what he looks at is a faithful representation of Nature. We may be permitted to cavil at two small points: There is a photograph of a fetal head, and the suboccipito-bregmatic diameter is marked, and defined as being a line drawn from midway between the foramen magnum and the occipital protuberance to the anterior fontanelle. This diameter, so defined, is of no importance obstetrically. It cannot be measured in the living child because the foramen magnum cannot be felt. The measurement in the sagittal plane that is important is the largest diameter that has to pass the vulva and stretch the perineum, and this is the sub-occipito-frontal, and should be defined as the measurement between the nape of the neck and the most distant point of the frontal suture. This point may or may not be the anterior fontanelle. The other point is that restitution and external rotation are described as the same thing. If so, why use two names? The difference between them used to be clearly defined by Matthews Duncan. Restitution is the restoring of the head to its natural relation to the shoulders—the undoing of the slight twist of the neck which brought the head into the antero-posterior diameter while the shoulders were in the oblique diameter of the pelvis. External rotation is this movement carried further by the rotation of the shoulders into the antero-posterior diameter. This may be a trifle, but it is well that words should be used accurately. The student who looks carefully through this *Atlas* will learn a great deal. The fourth section, which completes the work, illustrates transverse and face presentations, placenta prævia, accidental hæmorrhage, retained placenta, Caesarean section, pendulous belly, inversion of the uterus, and some of the instruments used in midwifery. The text is descriptive only, and of an elementary kind. In the section on rupture of the uterus we should like to have seen it more clearly insisted on that the obstacle to reduction is the contracted os internum, and the necessary condition for reposition is the dilatation of the os internum. The *Atlas* is not a substitute for a textbook on midwifery, but only an aid to impressing things on the reader's memory. We congratulate the editors on the completion of their work, which we hope a wide circle of readers may find helpful.

Until the present time, Professor FEHLING remarks in the preface to his book on operative midwifery, there has been only one kind of midwifery. But unfortunately, he says, there is growing a kind of surgical midwifery different from that of private practice. The object of his book⁵ is to show the general practitioner how far he may go, and when he should send his patient to the hospital. At present it is necessary, in the interest of the patient, to draw this line. It will be the object of the future so to train students that they may be masters of the whole field. In the first chapter of the book, which relates to antiseptics, the author shows himself a Listerian of the most pronounced Continental type, and between his hospital observances and the practice of the ordinary general practitioner there certainly is a difference, or at least we should have thought so. Does the German doctor attending a working man's wife in her labour wash and scrub his hands for ten minutes by the clock, and then put on indiarubber gloves? Medical fees are not high in Germany, and we should not be surprised to learn that the expense of indiarubber gloves, both by reason of their cost and their fragility, prohibited their use in private practice. The book is a series of clinical lectures. It does not profess to be exhaustive, but it is clear and practical, and we presume

fairly represents German practice. Like many of his brethren, Professor Febling does not know the best way of decapitating. He advises the clumsy instrument of Braun, by which the cervical vertebrae can be fractured, leaving the soft parts to be cut through with scissors. If he were acquainted with Ramsbotham's sharp hook, he would not have recommended anything else. He describes the axis-traction forceps, but does not advise its use, for the reason that continuous pressure on the child's head is not good. He does not know how easy an operation subcutaneous symphysiotomy is. He describes "pubiotomie" (*sic*), an operation which we cannot imagine a general practitioner with only average surgical skill and experience undertaking. Nor can we think that vaginal Caesarean section is a general practitioner's resource. Professor Febling mentions as an indication for this operation persistent retroflexion of the gravid uterus; not knowing, apparently, that in every such case that has been let alone natural delivery has taken place. The work is no doubt a good textbook for the average German student. Perhaps we are the subjects of insular prejudice when we say that we think there are better textbooks published in our own language.

The title of the book, *Das Auge des Geburtshelfers*,⁶ is metaphorical. Professor SELLEHM explains that the eye of the midwife (male or female) is, when practising that department of surgery, at the tip of the forefinger. The work consists of two parts. The first is a brief summary of the physiology of sensation. It is not up to date, for the author has apparently not heard of the great work done by Head, with the assistance of Sherren and Theodore Thompson. Dr. Selheim is aware that there are different kinds of sensation—as for light contact, deep pressure, heat and cold, etc.—but he has not attained to the meaning of "protopathic" and "epicritic" sensibility. The second part is an account of what an educated finger ought to be able to feel in the pelvis, and advice as to how a practitioner of midwifery should educate his sense of touch, and record observations made by that faculty. The student, the author points out, when he begins the study of midwifery, enters a new world, in which the sense of touch replaces that of sight. The trend of the work is to inculcate care, thoroughness, and accuracy. Its influence upon those who study it cannot but be good. It aims at forming sound methods rather than imparting information. It is laudable but limited.

The large sale of *Aids to Obstetrics*⁷ shows that it has been popular, and in its conciseness and clearness we discern the reasons for its popularity. For the present edition Dr. Nall, the original author, disclaims responsibility. Dr. LONGRIDGE has revised the book. There are a few things which we take to be errors, and we feel bound to point them out. At p. 132 the reader is told that "version or Caesarean section" is recommended for persistent retroversion of the gravid uterus. He should have been informed that natural delivery has taken place in every case that has not been interfered with. For placenta prævia, Caesarean section is said to be "good treatment." The latest collection of results that we know of—that of Dr. MUNRO KERR, published in 1904—shows an average mortality for this operation, when performed by the best operators and in the best hospitals in Europe, of 8 per cent. The mortality among cases treated according to the precepts of Braxton Hicks is less than half this. At p. 163 the author has copied from old books a recommendation to divide the neck by a piece of whipcord. He says not whether he has tried it, but we trow not, for he tells not how many hours it takes. Such an archaic futility and as an alternative to Ramsbotham's sharp hook on the same page, is a deplorable waste of space in a small book like this. But on the whole the revision has been well done.

THE ROENTGEN RAYS IN DIAGNOSIS AND TREATMENT.

The fact that the leading exponents of x-ray practice are also the most careful to point out its inevitable limitations is suggested by the appearance of Dr. ARNSPERGER'S substantial volume on the Roentgen examination of the organs of the chest and its results in physiology and pathology. The author, who was a pupil of William Erb, aims to bring the radiological method into harmony with the other diagnostic methods, rather than to assert its independence and self-sufficiency. The idea that these other methods are superfluous is, he says, a danger to straightforward x-ray procedure. Having thus given the keynote of the book, its scope may be indicated by saying that it is really a sort of guide-book to the perplexing x-ray shadows of the chest. Technical preliminaries occupy the author scarcely at all; for these he refers the reader to other text-books. Confining himself to the medical side of the question, he takes the scientific line of examining in the first place the normal thorax, and then devotes the larger portion of the volume to a critical review of the changes to be noted in injury and disease. All kinds of abnormal conditions are treated in turn, from cervical ribs to mediastinal tumours, but the interest centres in the lengthy section dealing with the localization of the shadows in phthisis. Dr. Arnsperger is sceptical as to the value of Williams's phenomenon, and states that he has found the diminished excursion of the diaphragm an early symptom in only 6 per cent. of his cases. In his opinion pleuritic adhesions, which are often absent in early tuberculous cases, are generally the cause of this limitation of movement. With regard to apical appearances he reiterates his former statement that the shadows seen in the diseased apex during deep inspiration sometimes become darker instead of lighter up. Enlargement and cessation of the bronchial glands he believes to be only a secondary and somewhat uncertain feature in early diagnosis. Very frequently remains of glandular swellings left from childhood cause confusion in a radiological examination. On the whole question he affirms that while the x-rays furnish a very good idea of the extent of the tuberculous process and of its infiltrated, cirrhotic, or cavernous character, they fail to give the evidence upon which to form a decision as to the clinical importance of the visible variations. It cannot be stated with certainty whether what is seen in an x-ray picture is a fresh process or an old scar. A number of radiograms are given in the appendix, but the author considers that the physiological movements produce so many different appearances that, in spite of improvements in technique on the photographic side, the screen examination is still to be preferred. Nevertheless, there are requirements, such as the detection of isolated tubercle, when the radiogram may be of more value than the screen. On the other hand, in considering the size of the heart, the single screen examination is open to many sources of error, and here comes in the use of the orthodiagraph. The absence of any index to such an elaborate work is a serious omission.

So noteworthy have been recent x-ray developments that Dr. H. E. SCHMIDT has found it necessary to issue a second and augmented edition of his compendium of Roentgen-therapy,² which was first published in 1904. One third of this concise treatise is devoted to the technique of interrupter, tube, dosimeter, etc., favourable mention being made of the newest dosimetric method of Schwarz. The author then discusses at length the indications for x-ray treatment in many dermatological and other conditions, including syphilis, in which he has found the tertiary ulceration yield to this therapy. An important chapter treats of the three forms of x-ray dermatitis, distinction being made between the erythema, skin atrophy with warty proliferation, and the sclerodermic condition with impeded movement of the muscles. He points out that the degree of sensitiveness differs with individuals and bears some relation to the general nutrition. In dealing with x-ray injuries from the forensic standpoint, he says

that cases of serious mischief to patients are now rare, but the possibility, particularly of testicular injuries to youths, needs to be borne in mind. He has been called as an expert in cases in which indemnification was demanded, and his list of precautions, the neglect of which most commonly gives rise to the allegations of malpractice, is instructive. The book will be useful to those who follow German details of technique and treatment.

NOTES ON BOOKS.

ALL medical men who contemplate "taking a ship" for the first time would be well advised in procuring a copy of Mr. J. F. ELLIOTT'S excellent little volume *Hints to Ship's Surgeons*.¹⁰ It can be read in an hour, and gives an immense amount of information of a practical kind. The young medical man who "signs on" for the first time, is almost necessarily ignorant to a large extent of some of the conditions under which he is about to practise his profession. This little book will inform him as to his relations to the Board of Trade, the owners of his vessel, the passengers, his fellow officers, and the crew. Incidentally it will warn him against many mistakes that would be the natural outcome of inexperience, and provide him with much useful advice as to treatment under the peculiar conditions that prevail aboard ship.

The fifteenth edition of *Chavasse's Advice to a Wife*¹¹ will fully maintain the reputation which has been won by its predecessors. As far as the medical advice given the book is quite modernized, and seems to contain all that a married woman ought to know without interfering with the proper function of the medical attendant. As several generations of mothers have now been trained on this book the language might be a little modernized also, and what the present editor calls the "chaty style" of the original author might be modified to suit the taste of the present generation. At least we would plead for the substitution of the word "woman" for "lady" in discussions of female sexual functions. The latter word in such a connection smacks of a kind of early Victorian "delicacy" which has become almost indecent to a modern ear.

*The Territorial Year Book*¹² contains a great deal of information about the Territorial Force and other matters likely to interest Territorials. It begins by reviewing the work of the past year, including the progress of the force and its developments, the changes and improvements in the medical department being specially noted. Details of how to enlist, dress, pay and allowances, training and instruction, and peace and war establishments, are then given, as well as particulars of the territorial divisions and brigades in the various districts and commands. Several pages are taken up with hints for camp and manoeuvres, and will be found of particular value to recruits. These are followed by hints on health and first aid, and if all men would follow the advice given there would be a good deal less of the minor ailments which are so frequent in camp and interfere with efficient training. Veterinary hints are not forgotten, and here again details are given, and, if studied by those mounted men who in civil life have not much to do with horses, will enable them to do their work more expeditiously and with greater advantage to themselves and the animals. We may add that a list of books, official and unofficial, and their prices is given, and will be found specially useful to officers or men desiring to make themselves proficient in technical subjects.

The second German edition of the work on tuberculosis by Drs. BANDELIER and ROEPKE was reviewed in our issue of November 14th last, p. 1501: it was then said that the book might be warmly recommended to the attention of all who have to treat tuberculosis in any of its forms, and readers will be glad to know that Dr. Ebert C. Morland has made a translation into English of this edition, which is published under the title *Tuberculin in Diagnosis and Treatment*.¹³

¹⁰ *Hints to Ship's Surgeons*. By J. F. Elliott, L.R.C.S., L.R.C.P.I. London: John Bale, Sons, and Danielsson, Ltd. 1908. (Cr. 8vo, pp. 64, 2s.)

¹¹ *Chavasse's Advice to a Wife on the Management of her own Health and on the Treatment of some of the Complaints incident to Pregnancy, Labour, and Suckling*. Fifteenth edition. Revised by G. D. Robinson, M.D., B.S., F.R.C.P. London: J. and A. Churchill. 1909. (Cr. 8vo, pp. 368, 2s. 6d.)

¹² *The Territorial Year Book*. 1909. London: Hodder and Stoughton. (Cr. 8vo, pp. 34, 9 maps and diagrams, 1s.)

¹³ *Tuberculin in Diagnosis and Treatment*. By Drs. Bandelier and Roepke. Translated from the second German edition by Ebert C. Morland, M.D., B.Sc. London, M.D. Berna. London: John Bale, Sons, and Danielsson, Limited. 1909. (Roy. 8vo, pp. 120, 7s. 6d.)

² *Die Röntgenuntersuchung der Brustorgane und ihre Ergebnisse für Physiologie und Pathologie*. Von Privatdozent Dr. Hans Arnsperger. Leipzig: F. C. W. Vogel. 1909. (Roy. 8vo, pp. 271, 34 figures in text and 27 plates. M. 12.)

³ *Kompendium der Röntgen-Therapie*. Von Dr. H. E. Schmidt. Second edition. Berlin: August Hirschwald. 1909. (Post 8vo, pp. 164; 36 figures. M. 3.)

The latest volume of the *Transactions of the American Laryngological Association* covers the proceedings of that body at its meeting last year, when the Association visited Montreal. Among the thirty-eight papers read were a series of three dealing with sinus disease, and another series of four which served as an introduction to an interesting discussion on recurrent and abductor paralysis of the larynx. The volume also supplies an index (names and subjects) to all papers which have been read before the society during the past ten years. The president at the meeting was Dr. Birkett, parts of whose interesting account of the history of medicine in the Province of Quebec between the years 1535 and 1838, have already been quoted in our Literary Notes.

It is impossible when the fetish of examination prevails to criticize unfavourably any book which accurately represents, however briefly, the facts which an unfortunate examinee has to produce for the ordeal. We can say this of Dr. MURRELL'S *Aids to Forensic Medicine*¹⁴ that they do present accurately the facts required for the above purpose; and probably the author himself will think that this is all that the "Aids" series requires; but we would like to add that Dr. Murrell possesses a faculty of expressing these facts in language pleasant to read, and that does not irritate by its style. The fact that the book has passed through six editions proves conclusively that it is found useful by those for whom it is written.

PHYSIOLOGICAL CHEMISTRY.

Hoppe-Seyler's name is still one to conjure with, and is rightly preserved both in the journal which he founded and in the book by which he is best known. At the time when he began his work his was the only handbook of physiological and pathological chemical analysis¹⁵ in Germany. At the present time the number is so great that teachers and students alike have a difficulty in making a selection. It is almost six years since Professor THIERFELDER edited the seventh edition, and in this time the changes in the science have been so sweeping that the book has had almost to be rewritten. As a practical laboratory guide it is, in our opinion, easily first, and we wish it continued success.

Professor HAWK has rewritten a good deal of his textbook, so as to bring it up to date, and in so doing has much improved it.¹⁶ The work still possesses some disadvantages as a guide for practical classes to which we referred in our review of the first edition. These relate mainly to matters of arrangement. The book, however, is extremely good and very complete. A special feature in it is the wealth and beauty of the illustrations. No properly equipped laboratory or library can afford to be without it.

CLINICAL THERAPEUTICS.

A textbook on clinical therapeutics¹⁷ which has achieved the distinction of a fifth edition needs but little introduction, and Dr. LEMOINE'S is essentially businesslike in its method of classification. An outline of the characteristic clinical features of each malady, followed by a summary of the symptoms which it produces, leads up to an account of the therapeutic measures, arranged under special headings. The instructions thus given are of necessity somewhat dogmatic, but on testing their accuracy and scope in some of the less common diseases we can commend them as trustworthy and fairly comprehensive. Vaccine treatment does not as yet seem to have found much favour in France, and radio-therapy is still in the experimental stage. Tuberculous disease is to be treated on hygienic and symptomatic lines only, no mention being made of the relative merits of serums or tuberculin. The whole work forms a handsome volume, written in very easy French, which has attained to its present proportions by successive stages from the very elementary book which first saw the light in 1896. A fuller index would add to its value as a work of easy reference, and still further justify its title to be a guide to everyday medicine.

¹⁴ *Aids to Forensic Medicine and Toxicology*. By W. Murrell, M.D., F.R.C.P. Seventh edition. London: Baillière, Tindall and Cox, 1908. (Fcap. 8vo, pp. 133. 2s. 6d.)

¹⁵ *Fests Hoppe-Seyler's Handbuch der physiologischen und pathologischen Chemie, Anleitung für Ärzte und Studierende*. Bearbeitet von Dr. H. Thierfelder. 8te Auflage. Berlin: A. Hirschwald, 1903. (Gr. 4to, pp. 874. Fig. 10, Taf. 1. M. 22.)

¹⁶ *Practical Physiological Chemistry*. By Philip B. Hawk, M.S., Ph.D., Professor of Physiological Chemistry in the University of Illinois. Second Edition. London: J. and A. Churchill, 1903. (Roy. 8vo, pp. 453, 126 figures in text, and 2 plates of absorption spectra. 16s.)

¹⁷ *Thérapeutique Médicale et Médicine Journalière*, by Dr. G. Lemoine, Professor of Clinical Medicine at Lille. Fifth edition. Paris: Vige Frères, 1903. (Roy. 8vo, pp. 1,123. Fr. 15.)

In the preface to his pocket-book of therapeutics,¹⁸ Dr. SCHNIRER explains that an earlier edition has received the flattery of plagiarism, which has been stopped by process of law. It is a little difficult to say whether this is mentioned by way of complaint or boast. For the rest the booklet contains a miscellany of prescriptions, sound enough in a sense, and very similar to those contained in various English works of the same sort. But this kind of potted therapeutics is open to grave objection, in whatever language it may be written.

MISCELLANEA.

The story of *Sir Guy and Lady Rannard*, by H. M. DICKINSON,¹⁹ is that of a millionaire madman and his wife. Regarded as an ordinary novel, perhaps, its interest lies chiefly in the picture painted of a woman who, marrying from ambition, begins to love her husband when she finds he needs her care. It is prolix in parts, but in the description of the skill and courage with which the wife endeavours to conceal her husband's mental state there is a decidedly truthful touch. There is skill, too, in the description of the development of the hero's insanity, though to the end most medical readers will remain in doubt as to the precise nature of his malady. Probably they will conclude that the author has had under observation cases both of volitional insanity and of general paralysis of the insane, and has confused their symptoms.

The play by Mr. ST. JOHN HANKIN,²⁰ named *The Last of the de Mullins*, is a clever impressionist sketch of a very old situation. Failing the arrival of a conventional festa, the heroine thinks it more sensible to eat her cake with a chance partner than let it mould in the cupboard. The usual fit of indigestion follows, but for this she refuses to accept either pity or forgiveness, deeming neither needed.

MEDICAL AND SURGICAL APPLIANCES.

A Suture Needle.

DR. G. H. PEAKE (Medical Mission, Fianarantsoa, Madagascar) has designed a suture needle which he has found useful in passing deep sutures in operations in the pelvis when, owing to the presence of the tumour or adhesions, there has not been room to secure easily the thread in the ordinary suture needle. The head of this needle, with the suture, can be seized with an ordinary pair of artery forceps, guided to it by the finger. The shaft is then easily withdrawn, the needle-head pulled up, and liberated by division of the suture: a double ligature is thus left under the structure to be tied. The extra needle-head, supplied with the handle, can be kept ready threaded in the instrument tray. The needle is made by the Holborn Surgical Instrument Company, Limited, Thavies Inn, Holborn Circus, London, E.C.

A Urine Collecting Bottle.

The annexed engraving shows a bottle which Messrs. Hewlett and Son, of Charlotte Street, E.C., are now making under the name of the "Handy Collecting Bottle." It is intended to facilitate the collection of samples of urine from ordinary receptacles, and seems well suited to its purpose. It holds

some 4 oz., and on its external surface has a roughened space on which the name of the patient can be written either in pen or in pencil. It is easy to clean, and its india-rubber stopper fits so well that when the bottle has been placed in the tin case, shown alongside it, it can be carried in the pocket without risk of leakage. Its price, bottle and container together, is 2s. 6d., extra bottles costing 1s. 6d. each.

SEVENTY-SEVENTH ANNUAL MEETING
OF THE
British Medical Association.
AT BELFAST, JULY, 1909.

SPORT AND TOURING IN IRELAND.

[FROM AN IRISH CORRESPONDENT.]

The Giant's Causeway.

may be taken for granted that the great majority of members attending the Annual Meeting of the Association in Belfast will spend a few days or weeks exploring some of the many beautiful districts in Ireland, or taking advantage of the facilities that country offers for sport in one or another form. It is the aim of this article to give some help to such members, and assist them in choosing what will best suit their tastes. When the choice is made, help in obtaining it will be given through the Honorary Local Secretaries, either by correspondence beforehand, or during the meeting.

First it should be said that, though Ireland is not a large country, neither is it one in which travel is rapid as a rule, so that, except for the motorist, it is a mistake to try to see the whole country on one visit. Dublin and Killarney may certainly be combined with Belfast, the Giant's Causeway, and Donegal in one trip, but unless one has had the fortune to be born under the Stars and Stripes, such a trip is likely to prove more exhausting than satisfying. The first piece of advice, then, is to choose a short tour and not hurry over it. As regards time, those who can arrange to take their holidays in July, before the meeting, are sure to have the best of it, for they get the long evenings, less crowded hotels and trains, and greater likelihood of fine weather. The last point leads to the remark that Irish weather has been greatly maligned, for though it rains often it seldom rains for long, and the sudden change from a dull and wet morning to a brilliant sunny afternoon among the Donegal or Kerry hills is a thing to be remembered for a lifetime.

MOTORING.

Some hints on motoring in Ireland may be of use to those members who think of taking over their cars. Irish roads, speaking generally, are rough, and a low-powered light car is the most suitable for them—say a car of 16 h.p. weighing not much more than a ton. There is a common tariff for cars on the cross-channel steamers, amounting to 30s. a car up to 10 cwt., and 1s. a cwt. over 10 cwt., owner's risk, or 25 per cent. extra at company's risk. The cars are well cared for on the journey.

Through Ireland generally the facilities for repairs and for obtaining supplies of petrol are quite good, and the hotels are accustomed to house cars. It is well to remember the frequent occurrence of hog-backed bridges and culverts, which render fast going dangerous, especially for a heavy car. As has been said above, Ireland is a small country, and it is possible to see a great deal of it in a fortnight's motoring. One might begin at Dublin, go by Killarney and round the coasts of Kerry and Clare to Galway, then through Connemara to Achill, by Sligo to Bundoran, and round the coasts of Donegal and Antrim to Belfast. But a far more enjoyable holiday will be spent if the trip is shortened, and taken easily, exploring some of the hills and valleys on foot. Innumerable side trips may be made, too, off the main route suggested, and one which the writer thinks quite unequalled in the British Isles is down the Dingle Peninsula from Tralee, co. Kerry, over Connor Hill Pass, and round Sleah Head, the

most westerly point of Europe. Given a fine clear day, the views of sea, island, and mountain are magnificent.

EXCURSIONS
FROM BELFAST.

Three excursions have been arranged for the Saturday after the meeting: (1) To the Giant's Causeway, (2) to Glenariff and round the Antrim Coast to Larne, (3) to Newcastle and round the co. Down coast to Warrenpoint.

The Giant's
Causeway.

This excursion, which

An Antrim Trout Stream.

will no doubt be the most popular of those on Saturday, will take the visitor from one end of co. Antrim to the other, through a picturesque stretch of country, chiefly agricultural, but very different from English agricultural districts. The small fields, thatched and white-washed farmhouses, occasional bogs, and frequent streams, are all typical of Irish scenery.

For the first few miles the line runs down the north shore of Belfast Lough, then reverses its direction and ascends the Antrim plateau, on which it keeps most of the

way to its terminus at Portrush. Just after leaving Antrim station a glimpse is got on the right hand side of the line of a very fine round tower, one of the most perfect of these interesting and puzzling remains of prehistoric Ireland. Halfway to Portrush a stop is made at Ballymena, where the line to Glenariffe, the second excursion, diverges to the right. Ballymena is a flourishing little market town, and the station, a model of neatness and convenience, is worth noticing. Soon after leaving it a real Irish bog on the right side of the line is passed. Piles of turf or peat are seen drying, and the bog is scored by the long dark lines of cuttings from which it has been taken. At Coleraine the main line goes off to the left to Londonderry, and a glimpse is got on the left of the Bann, a fine salmon river, which drains Lough Neagh. Then almost immediately the Atlantic Ocean is sighted, with Malin Head, the most northerly point of Ireland, running into it in the north-west. At Portrush, which it is correct to refer to as "the Brighton of the North," the electric tram is taken to the Causeway, eight miles off. The run is a splendid one—first through the links of the Royal Portrush Golf Club, and then along the cliffs with superb

which the stream forms some fine waterfalls, well worth seeing. After walking down the glen for about two miles the road is rejoined and the drive continued to the foot of the glen, 6 miles away, then round the splendid coast road 25 miles to Larne, stopping on the way to lunch at Carron Tower, built by one of the Londonderry family, and now an hotel. It is very beautifully situated on a height overlooking the channel and the Scottish coast, which at one point, a little to the north of this, is only 11 miles distant from the coast of Ireland. After lunch the drive will be resumed to Larne, whence train is taken 24 miles to Belfast.

The County Down Coast.

This excursion will appeal specially to those who enjoy mountain scenery, for the road from Newcastle to Warrenpoint lies round the base of the Mourne Mountains, the highest hills in Ulster. Slieve Donard, overlooking Newcastle, is 2,796 ft. high, and many of the others are not much less. As they rise steeply from the sea they show their height well, and, being a mass of granite, are singularly fine in outline.

Newcastle is reached in about an hour by express train

On the Links, Newcastle. Mourne Mountains in distance.

sea and rock views. A glimpse is got of Dunluce Castle, for centuries the stronghold of the Macdonnells. After passing the little town of Bushmills, chiefly famous for whiskey, the line passes over the river Bush, a fine salmon river, and shortly reaches its terminus, whence it is twenty minutes' walk down to the Causeway. There guides can be had who will expatiate till further notice on the geology, mythology, or theology of the district, according to the taste of the visitor. But after satisfying one's curiosity on the actual Causeway the visitor ought to do one of two things—either take a boat, if it is a fine and calm day, and visit the caves, or else walk round the cliff path, where the most glorious views of sea and headland are obtained, varying at every turn. The return journey will be made to Belfast by the same route.

Excursion to Parkmore and Glenariffe.

Parkmore, reached from Ballymena, on the line to Portrush, by a narrow-gauge line, is the highest station in Ireland, being about 1,000 ft. above the sea. It is on the edge of the Antrim plateau, at the head of Glenariffe, one of the most beautiful of the glens of Antrim. These glens are valleys cut deep into the plateau, and running down to the sea on the east side of the county. The head of Glenariffe is actually a gorge, worn by the water in the rock, in

from Belfast, the journey being through the good agricultural districts of County Down, and very picturesque. The district is one of the most prosperous in Ireland, a stronghold of the Ulster Scot. After passing the little town of Downpatrick, with a cathedral under whose shadow St. Patrick lies buried, the line enters rougher country, and approaches the sea at Dundrum Bay. Just before Newcastle is reached the golf links of the Royal County Down Golf Club are seen on the left side. It is on these fine links that the Belfast Cup, described in another column, will for the first time be played for on Friday, July 30th. From Newcastle the road to Warrenpoint, a distance of twenty-four miles, will be taken; it runs between the mountains and the sea, with fine views on every side. Near Warrenpoint it passes through Rostrevor, the favourite health resort of Ulster when a mild and sheltered situation is desired. Warrenpoint lies on the shores of the beautiful Carlingford Lough, and is the terminus of a branch of the Great Northern Railway. After dinner there the train will be taken back to Belfast.

not only dead fishing. In the short space at disposal it is impossible to deal with angling in Ireland generally, and the following

remarks are confined to districts easily reached from Belfast, and worth visiting about the time of the Annual Meeting. This is not the best time of year for angling, but it is by no means the worst, and it is often quite good if the weather is favourable. It is hardly necessary to say that the best angling must be paid for, but nevertheless really good sport, both salmon and trout fishing, may be had free at many hotels which have acquired the angling rights in their districts, and the charges at these hotels are generally very moderate compared with those usual in Scotland. Wherever the visitor fishes, he must take the £1 Government licence to angle for salmon or sea trout, or rather must take the licence within twenty-four hours of landing his first fish.

The Bann.

The river Bann, flowing north from Lough Neagh to the Atlantic, offers good salmon fishing in July. About the best to be had by a stray visitor would be got by going to the Mercer's Arms, at Kilrea, co. Derry, where the angling ticket costs about £1 a week, and a man and boat 5s. a day, with lunch for the man. There are some trout to be had here also, large fish, and the dry-fly fisherman has good chances. Early in August the prospects are equally good, provided the flax water is not down early. The pollution of the rivers by the water in which flax has been soaked is the curse of angling in north-eastern Ireland, for the fish are poisoned by it, and if not killed outright are too sick to rise. Portlennone, co. Antrim, is another good centre on the Bann. Accommodation may be had at a comfortable inn.

Cushendall.

At Cushendall, on the Antrim coast, free fishing may be had in several streams, with plenty of small brown trout. It is a delightful and picturesque district, suitable for a visitor who wants to explore the country, and only takes out his rod on a showery day.

County Donegal.

In County Donegal first-class fishing may be had at various places. Beginning in the north of the county, at Churchill, on Gartan Lough, small brown trout are plentiful, and in the Lennon river (free) there is a good chance of a salmon after a flood. At Rosapenna, which is noticed more at length under the head of golf, below, there is good fishing attached to the hotel up to the end of July, but after that date it is reserved by Lady Leitrim. Gweedore, on the west coast, is probably the best place for salmon, but as the rods are limited it is necessary to apply early (the Manager, Gweedore Hotel, co. Donegal). The charge

to visitors in the hotel for angling for salmon is 10s. a day. The river is heavily stocked, but needs a flood to make it fishable. The fish run small—about 7 lb.—and sea trout are plentiful. In the lakes, which are close by, are plenty of small brown trout, and on a good day one is likely to get some sea trout also. The gillie on the river receives 2s. 6d. a day and lunch, and rows the angler on the lake if he fishes it.

Dungloe is the centre for the Rosses fishery, best for sea trout, with the chance of a salmon. It is a dull place to stay at, with no resources except angling. Terms can be had from Mr. Hanlon, Dungloe.

Ardara is the centre for the Owenca and Owen-tocker rivers; the former is a good salmon and sea trout river (7s. 6d. per day), and the latter brown trout. Carrick offers good fishing—salmon, sea and brown trout—in two rivers free to visitors in the Glencolumbkille Hotel. It is a picturesque spot, and a good centre for excursions.

The river Erne, at Beleek or Ballyshannon, is among the best angling rivers of the kingdom, but the number of rods is limited, and generally all places are engaged months beforehand. The charge is five guineas a week, with 5s. a day and lunch to the gillie, and two fish a week are allowed to the angler. It is necessary to wade deep; the dry-fly fishing for trout is excellent, specially early in the season, and it is not expensive. (For full particulars write to the Manager, Erne Fishery, Beleek, co. Donegal.)

Lough Melvin, at the extreme south of the county, may be fished either from Bundoran, where there is a most comfortable railway hotel, and good golf links, but a rough drive to the Lough, or from Garrison, which is more primitive, but quite comfortable, and has the advantage of being on the Lough. The trout fishing is free; the angler pays 5s. a day for a boat and two men, and gives the men lunch. The fishing is most interesting, as not only Ferox, but the beautiful Gillaroo trout, rare black-fin trout,

The Royal County Down Golf Club, Club House and Slieve Donard Hotel, Newcastle, County Down.

A Newcastle Bunker.

(with so-called gizzard), and the locally called Sonaghan, may be got.

Single Days.

Plenty of single day angling excursions may be had from Belfast, but the choice should depend on the local weather conditions, and cannot be made long beforehand. Any member wanting such an excursion during the meeting should apply to the Honorary Local Secretaries, who will put him in communication with an angling member ready to help.

GOLF.

The choice which lies before a golfing member coming to Belfast is embarrassing in richness, so that a few hints as to the character of the chief links in the neighbourhood may be a help.

Carnalea.

The Royal Belfast, the oldest club in Ireland, has its home at Carnalea, about ten miles from Belfast, on the south shore of Belfast Lough, and reached quickly by a good train service on the County Down line. It is a nine hole course, and though on the sea, it is in many respects like an inland course, the ground being clay. The greens are good, and the bogey score is 39. There is a most comfortable club house, and the situation of the ground is beautiful, overlooking the Lough and the Channel.

Newcastle.

The Royal County Down, at Newcastle, is the seaside course most favoured by Belfast golfers. It is reached in about an hour from Belfast by express train, and is most beautifully situated at the foot of the Mourne Mountains, the highest hills in Ulster. On the edge of the links is the Slieve Donard Hotel, an excellent hotel owned and managed by the County Down Railway. Arrangements are being made for members of the Representative Meeting to spend the week end, July 24th to 26th, there. The course is about 6,400 yards, almost, if not quite, the longest in Ireland, and is most sporting. The bogey score is 80. The ground, which is an excellent natural one, has been carefully tended for about twenty years; the greens are well kept and are exceptionally large, and the course is very free from daisies in summer. Though a championship course, it is never overcrowded. It is here that the golfing members of the British Medical Association are invited to go on Friday, July 30th, to play for the Belfast Cup, presented by the golfing members of the Ulster Medical Society. Some particulars and an illustration of the cup will be found on p. 1426. Golfing members will be made honorary members of the County Down Club from Monday till Friday, and on Friday they will be entertained at luncheon and tea in the club house.

Portrush.

The Royal Portrush is one of the oldest clubs in Ireland, having been founded in 1838, and from the unrivalled situation of the championship course on the open Atlantic coast, is a favourite in summer. It is, indeed, often crowded at that season, and start is by ballot in the height of the

season. The course is first class in every respect, well laid out on magnificent natural ground, and well kept. Portrush is about two hours from Belfast by express train, and as it is a most popular seaside resort, there is ample accommodation of all sorts, though, like the links, the accommodation is apt to be rather crowded in the busy season. One further remark should be made on Portrush, and that is to say that the air possesses in a remarkable degree

stimulating or bracing qualities, which, according to many visitors, make a day there worth a week in any other place. It is hard to say why the air should vary much at places only a few miles apart, but vary it undoubtedly does, the coast only ten miles to the west being quite different.

Port Saloon.

Port Saloon, in County Donegal, is well out of the world, and quite beyond the range of the cheap tripper. It is reached in a few hours from Londonderry by train, boat, and car. There is a comfortable hotel,

with splendid natural links, the first tee just outside the hotel door. As only hotel visitors play there, it is never crowded. The course is a long 18-hole one, with a bogey of 82, and the greens present a wonderful variety of character. There is a little harbour and pier close to the hotel, where a dive or swim can be had before breakfast. There is some fishing in the neighbourhood.

Rosapenna.

Rosapenna, also in North Donegal, is somewhat similar to Port Saloon, and equally far from the madding crowd. It has a first-rate hotel, rather more fashionable, and excellent natural links running right round it. The course is about 6,000 yards with a bogey of 81. It is most splendidly situated, with the cliffs and bays of Sheep Haven on one side and Mulroy Bay on the other. There are numberless excursions to be made, and river, lake, and sea fishing for non-golfers.

Bundoran.

Bundoran is at the extreme south of County Donegal, and is a favourite summer resort. There is a good 18-hole course of about 5,500 yards, owned and kept in excellent order by the Great Northern Railway, which owns also a most comfortable hotel on the links. The course is never overcrowded, and, though not flat, is easy walking, with comparatively few hazards. The bogey is 77. Bundoran is the terminus of a branch of the Great Northern Railway, and is easily reached from both Belfast and Dublin.

Greenore.

Greenore, in County Louth, has also a good 18-hole

Royal Belfast Golf Club, Carnalea, County Down.

Golfing at Carnalea on Belfast Lough.

course and a very good hotel, owned and managed by the London and North-Western Railway Company, whose boats sail between Holyhead and Greenore daily. The course is just beside the station, and is well kept and interesting, with plenty of good hazards, both natural and artificial. The bogey is 77. Greenore is a remarkably bracing place, with lovely views of the Mourne Mountains, which rise steeply from the water on the other side of the picturesque Carlingford Lough.

VISITS OF HOSPITALS. Other Courses.

There are a number of inland courses round about Belfast as well as many shorter seaside courses in various watering places within easy reach of the city. Of the inland courses, the one most largely used by medical men and by the Queen's University staff is Malone, which is just a mile from the college, half the distance being traversed by the Stramillis tram, which passes the front gate of the college every few minutes. The course is an 18-hole one, over undulating ground, and quite good. It is about 5,400 yards in length, with a bogey of 77. Arrangements will be made for members of the Association to use the links during the week.

Golf Competition: The Belfast Cup.

The Ulster Medical Society has arranged to present

to the British Medical Association a cup, to be known as the "Belfast Cup." It is to be played for at annual meetings, and to be won out and out by any member winning it three times. It will be played for on the Friday of the Belfast meeting, on the fine links of the County Down Club at Newcastle, co. Down, kindly lent for the day by the council and members of the club. The play will be by bogey score. The cup is designed after the famous Ardagh Cup, now in the Kildare Street Museum in Dublin. The original, one of the finest examples of ancient Irish work, is composed of gold, silver, enamels, and jewels, and was, it is believed, meant for use as a chalice. The challenge cup will be of silver, about 9 in. high, with gilt panels and coloured enamel bosses; round it will be set stones representing the four Provinces of Ireland—the black pebble for Leinster, the white or Carnmoney pebble for Ulster, the red stone for Munster, and the green Connemara marble for Connaught.

The Belfast Cup.

To be played for at Newcastle on July 30th. Presented by the Ulster Medical Society.

CRICKET MATCH.

The North of Ireland Cricket Club, the premier club of Ulster, and one of the best in Ireland, has kindly offered to play a one-day match against a British Medical Association team. The beautifully turfed grounds of the club are only about five minutes' walk from Queen's College, where the Association will meet. The local executive will be very glad if some English cricketer will undertake to organize a team for the occasion; any one interested in the matter should communicate with one of the Honorary Local Secretaries.

LAUNCH.

The local executive has some reason to hope that there may be an opportunity during the annual meeting, of witnessing the launch of one of the great steamships for which the shipyards of the city of Belfast are famous. A large vessel for the Orient Line is at present on the stocks in Messrs. Workman, Clark, and Co.'s yard, and is expected to be launched in July. The exact date cannot be settled so far ahead, but if the firm can make it coincide with the visit of the Association to Belfast, it has courteously promised to do so.

BOATING.

The sheltered and picturesque waters of Belfast Lough are naturally much favoured by amateur sailors, and quite a large number of medical men regularly spend Saturday afternoon in sailing. Some of these have made arrangements to entertain brother sailors who may visit Belfast next month, and will give them an opportunity of trying their skill in managing a boat if they so wish.

The Royal North of Ireland Yacht Club will invite yachting members and their friends to a garden party at the club house at Cultra, about five miles from Belfast, on Friday afternoon, July 30th. A fleet of about fourteen of No. 2 and No. 3 classes Belfast Lough "one design" boats will be placed at the disposal of the visitors, and races will be got up if enough enter. It will greatly facilitate this if those interested in sailing, and intending to avail themselves of the club's hospitality, will write to that effect to the Honorary Local Secretaries at Queen's College, Belfast.

ARCHAEOLOGY.

Some inquiries have reached Belfast as to the objects of archaeological interest in the neighbourhood. In the city itself these are conspicuous by their absence, as it is entirely modern, and in Ulster generally there is not a great wealth of architecture of archaeological interest.

There are a number of old castles, the remains of the places fortified by the first Norman invaders, but these are generally of a very simple character, and attain interest more as picturesque objects in the landscape than on account of their architectural merits. There are few ecclesiastical remains, the only place of much interest near Belfast being Grey Abbey, co. Down, about sixteen miles from the city. It was a Cistercian abbey, founded in 1193 by the wife of John de Courci.

By far the most interesting antiquities in the district are the numerous prehistoric remains. The whole country is dotted over with Druidical altars or cromlechs, and one of the finest, surrounded by an immense earthen circular rampart, is only half an hour's drive from the college. There are also numbers of artificial caves or souterrains, but these are not easily explored without skilled guides. Of the well-known round towers there are

several within reach, the best being that at Antrim, mentioned above. The stump of one may be seen at Drumbo Church, within an easy drive of the college.

CONCLUSION.

Enough has been said to establish to the satisfaction of any member intending to be present at the annual meeting that he may feel sure, whatever his tastes in the matter of outdoor recreation, of being able to gratify them should he be able to take a holiday of a week or a fortnight either before or after. It would, of course, be easy for the visitor with more time at his disposal to go further afield, and to spend a month or more in extending the trip to the west and south-west of Ireland, where mountain scenery of great beauty, and a coast line of unequalled grandeur may be explored on foot with the help of the public cars, railways, and steamboats. But this article has been confined to the north of Ireland, which possesses special features of its own which may well detain the tourist, and where he may pleasantly fill in any short interval of leisure.

In a subsequent article some further account will be given of the immediate surroundings of Belfast and of the most convenient ways of reaching the city from various parts of England and Scotland.

THE MODERN TREATMENT OF FRACTURES.

DR. LUCAS-CHAMPIONNIÈRE, on his arrival in Cardiff on June 3rd, was accorded a cordial welcome. The eminent surgeon, who was accompanied by Madame Championnière and their two daughters, was met at the Cardiff station by the Lord Mayor (Alderman Lewis Morgan), Mr. Lynn Thomas, C.B., Mr. William Sheen, and Dr. Crawford Treasure (President of the Cardiff Medical Society).

After the usual formalities, the party, headed by mounted police, drove to the Mansion House, where during their stay in Cardiff Dr. Lucas-Championnière and family were the guests of the Lord Mayor. In the evening his lordship gave a private dinner at the Mansion House in honour of the visitors. The guests at the dinner included Dr. and Madame J. Lucas-Championnière, Mr. J. Lynn Thomas, C.B., and Mrs. Thomas, Dr. W. B. Crawford Treasure, J.P., Mrs. Treasure, Dr. F. P. S. Cresswell, Dr. H. E. Skyrme and Mrs. Skyrme, Mr. Wm. Sheen and Mrs. Sheen, Dr. Wm. Martin and Mrs. Martin, Dr. C. T. Vachell and Mrs. Vachell, Dr. W. T. Edwards, J.P., the Deputy Mayor (Councillor J. W. Courtis, J.P.), Dr. D. R. Paterson and Mrs. Paterson, the Misses Championnière, and the Misses Lewis Morgan.

MEETING OF THE CARDIFF MEDICAL SOCIETY.

Address by

M. LUCAS-CHAMPIONNIÈRE.

DR. CRAWFORD TREASURE, President of the Cardiff Medical Society, took the chair at the annual meeting of the society on Friday afternoon, June 4th. Owing to the large attendance, the meeting was held in the theatre of the Engineers' Institute, which was crowded by members of the society and other medical men who had accepted the invitation to be present.

The PRESIDENT, addressing M. Lucas-Championnière in French, welcomed him to Cardiff, and thanked him for honouring the society by undertaking to give the annual address. He recalled the fact that Professor Kocher, of Berne, had delivered the address two years ago, and the society was proud that his successor as President of the International Society of Surgery had become his successor also as the orator of the Cardiff Medical Society. The medical profession in Great Britain welcomed M. Lucas-Championnière with the greater cordiality because it was by no means his first visit to these islands and because he had taken back from his first visit an appreciation of the great principle propounded by Lister, for the reception of which his mind had been prepared by his study of the researches of Pasteur. Dr. Lucas-Championnière had been the earliest and the most convincing exponent of Listerism in France, but his name would be imperishably associated with the great reform he had himself introduced in the treatment of fractures, and he called upon him to deliver his address on that subject.

M. LUCAS-CHAMPIONNIÈRE, who on rising was received with loud applause, then delivered in English the address which is published at p. 1397. At its conclusion he was again much applauded, and the applause was renewed when he briefly acknowledged the presentation to him by the President of the diploma of honorary membership of the society.

A vote of thanks to the orator was moved by Dr. E. TENISON COLLINS, President-elect of the Society, in which he expressed his sense of the compliment paid to the society, to Cardiff, and to English surgery, and concluded by expressing in French to M. Lucas-Championnière the pleasure with which all present had listened to his lucid and interesting address.

Dr. T. D. GRIFFITHS, of Swansea, ex-President of the British Medical Association, in seconding, expressed his delight at the chance of hearing such a master of surgery. In the admirable address there were valuable lessons to the physician as well as to the surgeon. Their illustrious guest had emphasized the necessity for mobilization in the cure of fracture. By inference the physician could not help feeling that there was a lesson also for him as to the necessity of systematic movement, of sensible exercise, in prolonging life. As old age came, there came too stiffness in the joints—immobility. Old men properly exercised would hear the advancing motor car and would be able to step aside, and the sensible physician would have patients who would constantly be congratulated upon their smartness of appearance and comparative quickness of action. It had been a lecture full of suggestion to its hearers, it was a lecture that would be historical.

Mr. CLEMENT LUCAS supported the resolution in a few words, commending the suggestiveness of the address, and congratulating the society upon having enjoyed the honour of a visit from the greatest French surgeon of his generation.

PRESENTATION OF

THE LYNN THOMAS AND SKYRME FUND.

On the same evening the annual dinner of the Cardiff Medical Society was held at the Royal Hotel, the gathering being one of the largest and most representative of the medical profession that has ever been held in the Welsh metropolis.

Dr. CRAWFORD TREASURE, J.P., President of the Society, was in the chair, and on his right sat the guest of the evening, Dr. J. Lucas-Championnière (Paris), and on his left the Lord Mayor of Cardiff.

After the usual loyal toasts had been duly honoured,

The CHAIRMAN gave the toast of "Our Illustrious Guest," and in so doing said it would ill become him to enter into a description of the magnificent work in surgery which Dr. Lucas-Championnière had accomplished. He had followed in the footsteps of Pasteur, to whom medicine and surgery owed so much to-day. The work that their guest had done, and was still doing, was a great one. To have introduced the antiseptic system into France was an achievement of the highest

order; to have applied that system in the way he had and which had resulted in the reduction of mortality among women was also a great achievement; and now, to crown the labours of years, he had introduced a system which promised to revolutionize the treatment of fractures. The fame of their guest was not confined to his own country, but was international, and they honoured in him the head of the International Surgical Society.

The toast was drunk with musical honours.

Dr. LUCAS-CHAMPIONNIÈRE, in a brief response, said he must thank them all, both on behalf of himself and his wife and daughters, for their extreme kindness, and they felt especially grateful to the Lord Mayor and Lady Mayores for their hospitality. They had all made them feel at home. He would content himself with asking them to accept his heartiest thanks for the cordial way in which his health had been honoured.

Mr. WILLIAM SHEEN, who had acted as honorary secretary for the Lynn Thomas and Skyrme Fund, then made a statement regarding the initiation and progress of that movement. He said he might remind them that the case concerning which the action was brought occurred in July, 1904, and the first trial was in December, 1905, and the second trial in November, 1906. The plaintiff claimed £2,000 damages, but was only awarded £100. The total expenses of the trial were large. When the plaintiff's costs had been taxed and the Medical Defence Union had paid £928, there remained to be paid a sum of £3,200. At once the feeling of the medical profession

JUST LUCAS-CHAMPIONNIÈRE.

was made manifest with regard to it by a dinner held in Cardiff six days after the trial, at which 110 medical men attended, and which was the largest gathering of the kind that had then been held in that city. As soon as possible afterwards steps were taken to open a fund, and the credit for the initiation of this was due to Dr. Maclean, Mr. Edmund Owen, Mr. Robert Jones, and the editors of the two leading medical papers, to whom he would like to express their feelings of gratitude. As a result of the efforts of those gentlemen there was published at the end of March, 1908, a document known as "The Appeal," signed by over ninety leading men of the profession throughout the kingdom: they were all men of position, and included the President of the British Medical Association, the representatives of medical societies all over the country and of the hospitals. This appeal was widely circulated, and as a result during a period of four months there was collected for the fund no less than £1,788. When the expenses had been paid, the two gentlemen who had been involved in the matter would each receive £800, or just about half the expense to which they had actually been put. He understood that so large a sum had never been collected for such a case before. There were 2,000 subscribers, and it was interesting to know that of these 200 gave sums of half a crown. In conclusion, Mr. Sheen said that the work he had been able to do in this matter had been a labour of love.

Mr. EDMUND OWEN congratulated the Cardiff Medical Society upon the tremendous success of the gatherings that afternoon and evening. It must have been a great comfort to Mr. Lynn Thomas and Dr. Skyrme to know that in their time of trial—or he might say of trials—there was not only the profession of Cardiff standing by them but the profession of the whole of Great Britain and of the whole Empire. It was not in mortals to command success, but when medical men had done all they could to deserve it and had not altogether succeeded in attaining it, they deserved the sympathy of every member of their profession. Mr. Lynn Thomas and Dr. Skyrme had come well through their ordeal, but the verdict of the courts was against them. That day it had been shown that the verdict of the profession was with them, and in an affair of this sort, where a man's brain and heart and honour and conscience were concerned, it was much better, he ventured to believe, to have the verdict of the profession than of the court; and he was quite certain that they would not like the verdicts reversed. He was sure that all would agree that it was exceedingly fit and proper that Dr. Lucas-Championnière be asked to make that presentation. Their distinguished guest that evening was a disciple of Lister, and from being a disciple he became an apostle; the amount of good that he had done was immeasurable. When their guest came over impressed with the Listerian doctrine to see Lister in 1863, he followed him to Glasgow, and he followed him in 1875 to Edinburgh, and it was in these cities that he acquired that slight Scottish accent which they had noticed that evening. The fact that Dr. Lucas-Championnière was the President of the International Society rendered that gathering one of almost international importance. If it did not actually do that, their distinguished guest was doing what their dear King had done, and what Lansdowne and Edward Grey and Delcassé and Loubet had done—putting brick by brick into the *entente cordiale*.

Sir ALFRED THOMAS, M.P., in a brief speech, said how much pleasure it gave him to be present and to speak as a layman of his friends, Mr. Lynn Thomas and Dr. Skyrme. Mr. Lynn Thomas was an honour, not only to his profession, but to Cardiff and to the little country that gave him birth. He knew that Mr. Lynn Thomas had the courage

of his convictions, and, to quote in English a Welsh triad, it might be said of him that he had an eye to see Nature, a heart to love Nature, and the courage to follow Nature. He rejoiced at the ample vindication of Mr. Lynn Thomas and Dr. Skyrme that evening. He could not forget the splendid work that they and other members of their profession had done for the Medical School of Cardiff, in connexion with the foundation of which the names of W. T. Edwards and Daniel Jones would ever be associated.

Mr. MANSELL MOCLLIN (Senior Surgeon to the London Hospital) said that he was very glad to have the opportunity of speaking, for two reasons, one was that Mr. Lynn Thomas and Dr. Skyrme were two of his oldest friends, men with whom he had worked and whose word he could rely upon down to the ground. The other reason was that that occasion was, he believed, unique. He did not think there had ever been a testimonial presented under circumstances similar to this—a testimonial raised not from Cardiff, or Wales, or England only, but supported by the whole world. Its success was due simply to the fact that the medical profession believed in the justice of its cause. Larger amounts had been subscribed on occasions where there was some question of charity, but there was no such question here, and the numbers of those who subscribed showed that the medical profession believed in the justice of the appeal.

If it ever became his lot to have any such work done for him he could only hope that it would fall into the hands of Mr. William Sheen, who had done such excellent service as honorary secretary in this case.

Dr. LUCAS-CHAMPIONNIÈRE then made the presentation, Mr. Lynn Thomas and Dr. Skyrme walking arm in arm amidst a scene of great enthusiasm to the head of the banquetting hall. In making the presentation, Dr. Lucas-Championnière said he was proud to be present on that occasion and to have the honour of making the presentation. The occasion was not merely British, but had an international character.

Mr. LYNN THOMAS, who had a splendid reception on rising to respond, said he desired to thank them all for their very warm reception. That was, indeed, in his life a very memorable event. It had awakened what he had only very little realized till within the past

twenty-four hours. He had, he believed, ever since the verdict in the court, enjoyed the confidence of his brother medical men, but he had not an idea till quite recently that members of the profession could feel assured that there was an invisible hand which would render help to any member when accused wrongly of not doing his duty. That was a thing of which any profession might be very proud. He desired first of all to thank their guest of the evening, because by his presence he was not only paying a compliment to the Cardiff Medical Society, but to the whole British Empire. He looked upon him as a prophet from the East, travelling West. He (the speaker) would also like to take the opportunity of thanking his colleague, Mr. William Sheen, for the kind way in which he had taken up the matter of the testimonial. His action had cemented the friendship existing between them. He also desired to express his gratitude to the editors of the *Lancet* and the *BRITISH MEDICAL JOURNAL*, the two most powerful journals in the medical profession in the British Empire. The case which had come before the courts was one that affected every member of the profession, and he was gratified indeed to know that the testimonial had been subscribed to by no less than 2,000—from Lord Lister, the head of their profession, to many medical men in the smallest villages. It was in 1892 that he paid his first visit to Paris, and on that occasion he saw their distinguished guest treating certain types of fractures in a way that he had not seen before and which had surprised him, but he had also seen their guest doing ordinary opera-

tive surgery, and was very much impressed with his skill and care, so that he was prepared to believe that his method of treating fractures was worthy of study. In 1895 their guest brought out his great book, and a careful perusal of it, and further opportunities of observing M. Lucas-Championnière's practice, had made him one of their guest's disciples. He had a confession to make, and it was that he experimented once on a patient. That experiment was an extension of the principle laid down by Dr. Lucas-Championnière. The patient had ruptured his tendo Achillis. Mr. Lynn Thomas thought what their guest would have done under similar circumstances, and decided to follow out the treatment as in fractures. It was carried out with a measure of success quite satisfactory to the patient. He had reported the case in the *Barrish Medical Journal*, and he would like to tell them that that patient was himself. On one occasion he was returning from Paris; the sea was very rough, and some of those on deck had on occasions to clutch anything near when the vessel rolled. One gentleman near him used a word that was very familiar in the English language, and he (the speaker) asked him if he was hurt. He replied that he had strained his wrist, adding, "I broke my wrist a month ago." So he (the speaker), thinking for once in his life he would play the part of a Sherlock Holmes, said, "You have been under Dr. Lucas-Championnière." The gentleman turned and exclaimed, "How do you know?" "Because," was the reply, "it is only by his method that you would be able to use your hand within a month." In conclusion, the speaker again tendered his grateful thanks for all the sympathy he had received.

Dr. H. E. SKYMER, who was heartily received, said he wanted to express to them in the simplest words of sincerity the gratitude which he felt for the sympathy of the profession extended to Mr. Lynn Thomas and himself, and also for the practical form which that sympathy had assumed in generous contributions to the fund raised to reimburse their monetary loss, the intention being much more comforting than the actual money contribution. The considerable cost to which they were put was incurred from a sense of the necessity of conserving the interests of the profession at large, which was made especially apparent to them by the first trial at Cardiff. The knowledge that they were not fighting their own battle only, but that of the profession generally, induced them to employ the best possible counsel at any cost, the vital principle involved in the action being the right of every medical practitioner to use his discretion under any circumstances. One practical result of the action had been that the two medical protection societies who formerly undertook the cost of ordinary counsel for the defence only had since made arrangements with insurance companies, which, in consideration of a small annual subscription, undertook the payment of any damages that might be awarded and the taxed costs up to a certain amount involved by an adverse verdict—a substantial consideration to which he would call the attention of every medical man.

The toast of "The Visitors" was submitted by Dr. D. R. PATTERSON.

The LORD MAYOR OF CARDIFF expressed the pleasure with which he had listened to Dr. Lucas-Championnière's address and taken part in giving him a civic welcome to Cardiff.

Dr. SQUIRE SPRIGGE said that he was very glad to be present on what he considered to be a professional occasion of the highest importance, but, as the significance of the meeting had already been so eloquently indicated by previous speakers, he would confine his words to one particular point—namely, the manner in which the appeal to the profession was made. That manner was wholly admirable. The statement of the case in the medical press was studiously fair, and every point made was, or could be, vouched for by first-class surgical opinion. The original letter of appeal was based on broad grounds, without a touch of bitterness or personal recrimination in it; it was signed by names eminent in the medical world as professors, consultants and leaders generally, and received a remarkable scientific endorsement from the Continent and the United States. The success of the movement was assured by the manner in which it was inaugurated not less than by the righteousness of the cause advocated.

Dr. DAWSON WILLIAMS, who was also called upon to respond, said that the movement which reached its final

stage on that occasion owed nothing of its success to personal considerations. It was a movement to vindicate the right to freedom of thought. The claim to that right was no new thing for it had led to the foundation of the mediaeval universities, but it was appropriate enough that this most recent defence of the principle should have originated in Wales, for the people of the principality had in comparatively recent times been impelled, by a punctilious adherence to that principle, willingly to make many sacrifices. In the exercise of the medical art, freedom of thought implied freedom to act for the best according to the best knowledge of the day. In conclusion he said that he was commissioned to state that Dr. Rayner, Treasurer of the British Medical Association, had intended to be present, but was detained in London by pressure of business. Dr. Davy too, who, when President of the Association, had taken a warm interest in the initiation of the movement, was also unfortunately detained at the last moment.

The Rev. A. HENDERSON (Vicar of Cardiff), submitted the toast of "The President," who responded.

During the proceedings an excellent programme of vocal and instrumental music was performed by Mr. Arthur Angle and party.

MEDICAL PRACTITIONERS AND THE FINANCE BILL.

IN THE *BRITISH MEDICAL JOURNAL* for May 8th, 1909, an article was published on the Budget in its relations to the medical profession. The novel and complicated character of several of the proposals of the Chancellor of the Exchequer made it inevitable that many points should remain more or less obscure pending the introduction of the Finance Bill. After prolonged discussion of the Budget resolutions, the bill was introduced just before the Whitsuntide holidays, and a perusal of its clauses renders it possible to clear up several difficulties and to remove a number of misapprehensions.

Income Tax.

The income tax proposals were summarized in our former article, and we find comparatively little in the Finance Bill that was not there referred to. There are, however, some interesting features which may be touched upon. The first of these is the method of estimating the income for the purposes of the supertax on total incomes exceeding £5,000. Clause 47 provides that the total income is to be taken as "the total income . . . from all sources for the previous year, estimated . . . as the total income . . . is estimated for the purposes of exemptions or abatements. . . ." This proposal seems a wise one, as tending to simplicity, so far as simplicity is possible in income tax matters. The practitioner who is liable to pay supertax will not be required to enter into an elaborate calculation in order to make his return; he will simply insert on the form the amount of income under each head on which he paid tax during the previous year, and the aggregate of these amounts, less an abatement of £3,000, will be the amount on which he will be called upon to pay the supertax of 6d. in the £. Thus, in making a return for the current year, 1909-10, for the purposes of the supertax, the practitioner will insert as his professional profits, not the amount of his estimated income for 1909, nor the amount of his realized income for 1908, but the amount on which he was assessed to the ordinary income tax in 1908, which, as our readers are aware, represents the average profits realized during 1905, 1906, and 1907. His income from appointments must similarly be taken at the amount on which he paid tax in 1908, and so too with dividends, rents, interest, and any other private income. Though possessing the merit of simplicity, this system involves two possible sources of hardship. A careless taxpayer who was over-assessed in 1908, and did not trouble to appeal in due time, will again suffer this year, as the amount of the excessive assessment will be taken for the purposes of supertax. Again, a person whose income exceeded £5,000 last year will pay supertax this year, although he may be now receiving considerably less than £5,000 a year. It should, however, in fairness be stated that a person whose income was less than £5,000 last year will pay no supertax, although his income may greatly exceed that amount this year.

Medical men who own considerable property will be interested to learn that in reckoning income for the pur-

poses of supertax a special deduction will be made for expenses of management of 5 per cent. of the annual value of the property. From the wording of the clause it appears that this deduction will be allowed whether any expenses of management are actually incurred or not.

Professional profits are, for the purposes of the ordinary income tax, dealt with by local or district commissioners, unless the option is exercised of claiming to be assessed by the special commissioners, a body of paid officials appointed by the Treasury. The supertax is to be assessed exclusively by these special commissioners, who are to make regulations for the rendering of returns and for carrying the provisions of this part of the bill into effect. The selection of the special commissioners to deal with the supertax is probably due to the feeling that persons with large incomes would object to the disclosure of all their circumstances to their friends and neighbours, and possibly to their rivals, and therefore would prefer to be assessed by a body of officials rather than by local unpaid commissioners.

All persons on whom the prescribed notices are served are to make returns whether they are or are not chargeable with supertax, and every person who is liable to pay this tax is required to give notice to the special commissioners that he is chargeable before September 30th, annually. This requirement is doubtless intended to catch persons whom the taxing authorities might omit to serve with return forms. The penalty for failure to make returns or to give the notice referred to is £50, and, after judgement has been given for that penalty, a further penalty of £50 a day is incurred for every day during which the failure continues. It is obvious that attempted evasion of the supertax will be extremely dangerous.

A time limit of three years after the end of the year of assessment is imposed for the making of assessments to supertax. This corresponds with the limits applicable to the ordinary income tax.

With regard to the ordinary income tax, Clause 49 makes it clear that the allowances of £10 for each child, which are to be granted where the total income does not exceed £500, are to be made primarily from the earned income—that is, at the rate of ninepence. This clause also provides that the expressions "child" and "children" shall include stepchild and stepchildren, but not an illegitimate child or illegitimate children. This is in accordance with what had been generally anticipated.

It is to be noted that practitioners whose total incomes lie between £2,000 and £3,000, and to whom the reduced rate of one shilling will apply for 1909, so far as their incomes are earned, must make their claims for relief by sending declarations setting out their total incomes before September 30th, 1909. Attention is called to the fact that the words are *before*, and not *on or before*, September 30th. Failure to notice this distinction was the cause of a good deal of misapprehension and some disappointment two years ago, when the relief in respect of earned income was originally introduced.

By Clause 50 of the Bill persons who reside out of the United Kingdom but derive income therefrom will cease to be entitled to the exemptions and abatements applicable to residents in this country. This provision is novel as regards British income tax, although it is a feature of several foreign and colonial systems. Retired medical men drawing their incomes from this country, who have gone to reside abroad may find their pockets adversely affected by this proposal.

Motor Cars.

The new scale for licences for motor cars was given in the article already referred to, and is based upon the horse power of the cars. The unit of horse power is to be calculated in accordance with regulations to be made by the Treasury for the purpose. Medical automobilists are to pay only one-half of the full rates, and we quote in full the sub-clause conferring this relief.

66 (4).—If a duly qualified medical practitioner proves to the satisfaction of the Commissioners or council by whom the licence is granted that any motor car kept by him is kept for the purpose of his profession, he shall be entitled to an allowance in respect of the duty payable under this section on the car equal to half the amount of duty so payable.

It is interesting to observe that the relief applies to a car "kept for the purpose of his profession." The word "exclusively" does not appear in this expression, so that it is reasonable to suppose that a car kept by a doctor for

professional purposes, and principally so used, will not be charged with the higher rate of licence duty merely because it may be used occasionally for private purposes. This interpretation seems, at any rate, to be fair and equitable.

Disappointment has been expressed at the refusal of the Chancellor to extend the principle of "half rates" to the tax on petrol used by doctors for their cars. It is to be hoped that some concession on this point may be made during the passage of the bill through the House of Commons. That medical men are not entitled to this rebate as the bill stands is clear from the fifth schedule, which contains the conditions under which relief is to be granted. It runs as follows:

REBATE OF MOTOR SPIRIT DUTY.

Motor spirit used for the purpose of supplying motive power:—
1. To a motor car which is constructed or adapted for use, and is used solely, for the conveyance of any goods or burden in the course of trade or husbandry, and whereon the Christian name and surname and place of abode or place of business of the person, or the name or style and principal or only place of business of the company or firm keeping the same, shall be legibly and visibly printed in letters of not less than one inch in length.

Death Duties and Life Assurance.

The clauses imposing the increased death duties contain no provision of special import to the medical profession, although, in common with other members of the taxpaying community, they will probably find it increasingly necessary to make some provision by life assurance to meet the considerable burden which this group of taxes now imposes. This form of providing for the death duties has the incidental effect of reducing the practitioner's income tax, for, as is well known, the amount of income applied in payment of life assurance premiums is, subject to a limit of one-sixth of the total income, allowed as a deduction from the assessment.

Spirit Duty.

The increased stamp and tobacco duties and liquor licences call for no special comment in this article. With regard to the spirit duty, we may be allowed to reiterate the opinion that the manufacture of medicine should be allowed a special rebate of the additional duty imposed under this head. No provision for this rebate appears in the Finance Bill, and it can be introduced only by a direct amendment in Committee. We venture to express the hope that the Government will see its way to the acceptance of such an amendment in due course, for, as has been pointed out, an increase in the cost of medicines must fall to some extent upon the poorer classes—a result which we take to be directly contrary to the intentions of the present Administration.

Land Values.

We have left until the last the proposals for the imposition of duties on land values, and, as they do not affect members of the medical profession as a class, our explanations and comments will be brief. Three duties are to be imposed: A duty of 20 per cent. on increment value, payable on every occasion of the sale of land, or of any interest therein, or on death; a reversion duty of 10 per cent. on the determination of any lease, the original term of which exceeded twenty-one years, to be levied on the value of the benefit accruing to the lessor by reason of the determination of the lease; and an annual duty of one half-penny in the pound on the capital value of undeveloped land. It is claimed by the advocates of this tax that its effect will be to force development, to bring into the market building land which is now being held up for excessive prices, and, by reducing rents, to assist in the solution of the problem of the better housing of the working classes. On this highly controversial political question we express no opinion, merely remarking that members of the medical profession will welcome any measure which substantially tends to the improvement of the conditions of the life of the poorer members of the community. In any case, we rejoice to observe that the bill contains exemptions from undeveloped land duty for parks, gardens, and open spaces which are open to the public as of right, or to which reasonable access is granted to the public, where the Commissioners of Inland Revenue are satisfied that that access is of benefit to the public as contributing to the amenity of the locality. Similarly, land used for the purposes of games or recreation is to be exempted on like conditions,

THE FINANCIAL PROSPECTS OF MEDICINE.

INTRODUCTORY.

AMONG all classes of society complaints of hard times have ever been common, and medical men have probably never been an exception to the general rule. During the past few years, however, allegations of undue difficulty in making an adequate income have been increasingly frequent. They have come, moreover, not only from comparative novices in the practice of medicine as a livelihood, but from those whose knowledge and experience in medicine as a craft fall in nowise short of their professional attainments—from men who never forget the personal equation and are just as skilful in dealing with patients as in diagnosing their diseases.

Whether medicine when handled by men of average capacity and average ability is a less efficient money-making machine now than formerly is a question on which there is perhaps room for more than one opinion. No answer could be deemed unimpeachably correct which did not take into consideration a multiplicity of factors, including such minor points as differences in present and past general standards of life, the comparative expense of working a practice now and at earlier dates, variations in the value of money and consequently in the adequacy or inadequacy of the fees commonly received formerly and now.

Clearly, therefore, the question mentioned covers a very wide ground, and this article is not intended to supply a complete answer, the point considered being of a somewhat narrower character. It is as follows:

Assuming that complaints of hard times among medical men are well founded, are there any specific factors which might serve sufficiently to explain and justify their existence?

In other words, are there any material differences in the conditions of medicine at the present time as compared with the recent past which, so far as the general mass of medical men are concerned, would be likely to make it a less paying occupation than it was formerly?

Probably every medical man who has been long in practice could suggest some circumstance more or less of this order, but at the bottom of the whole question lies a factor the value of which cannot be determined by any man's personal experience; moreover, it is one not easy to define by a single phrase.

The clearest way of stating this factor is to ask whether the profession at the present time is overstocked or understocked as compared with the past. Put in this way we have a definite issue which can be considered with reference to the profession of medicine on the same general lines as would be followed in relation to any other occupation or trade. Overstocking in any of these may be brought about in a great number of different ways. Thus:

1. The demand may fall while the supply remains the same.
2. The supply may increase more rapidly than the demand.
3. Irrespective of any alteration in the ratio between demand and supply, the calling may be overstocked owing to new fashions of meeting the demand being invented.
4. Or any of these factors may be combined.

Each of these factors constitutes a separate question, and the order in which they are placed is perhaps the most natural one. In applying them, however, to medicine, a variation of sequence will be convenient. Furthermore, since the main question is not one of absolute but of relative overstocking, it is necessary to determine the period over which the investigation should be carried.

Provided that the same data are obtainable throughout, the period should be as long as possible; hence the years from 1881 to 1903 have been chosen, this period of twenty-eight years presenting the further advantage that a large proportion of the men who were at work at the beginning of it are either still in practice or have only recently retired.

The geographic extent of the investigation is also of importance, in order still further to ensure the comparability of the data obtained. On this point it should be said that soon after the investigation commenced it became clear that if it were extended to the whole of the British Isles it would be difficult to avoid certain possible sources of error. In Scotland and in Ireland the courses followed by socio-political matters have not been identical either with one another or with those of England and Wales. The figures given, therefore, relate only to England and

Wales. At the same time, however, it may be said that investigation regarding Ireland and Scotland was carried on sufficiently far to enable it to be stated with some assurance that, if an investigation were completed regarding each of these countries separately, the broader conclusions derivable would be identical with those hereinafter shown to be deducible from investigation of the position of the medical profession in England and Wales.

The ground being thus cleared, the method of investigation and the results may now be detailed.

POSSIBLE PATIENTS AND ACTUAL MEDICAL MEN.

It is necessary to assume for the moment that the demand for the work represented by the labour of medical men is just as great as ever; or, in other words, that of the four factors mentioned No. 1 has not been operative. No. 2 factor is thus reached, and applies to the medical profession in the following fashion:

Any community of, say, a thousand people may be regarded as a thousand possible patients, and, assuming that their liability to sickness remains the same in any two years, the demand for medical work will remain the same in the two periods. If, however, the number of medical men ready to do that work alters, the supply will vary accordingly, and comparative understocking or the reverse at once be created. Hence the ratio between the medical population or the actual workers and the general population or possible patients, and its variations year by year are both points of interest; while the difference between the ratios at the beginning and at the end of the period will show the presence or absence of relative overstocking so far as factor No. 2 is a conclusive test.

This information is supplied by Table A, in which the general population is the total number of persons living at

TABLE A.—Possible Patients and Actual Medical Men.

Year.	Col. 1. Number of Medical Men.	Col. 2. Rate of Increase.	Col. 3. Population.	Col. 4. Rate of Increase.	Col. 5. Ratio of Population to Medical Men.
1881	15,308	—	25,046,142	—	1,700.4
1882	15,783	0.48	26,334,942	1.10	1,710.9
1883	15,827	2.88	26,626,949	1.11	1,681.5

the middle of each year, as calculated by logarithms on the basis of the decennial increase ascertained to have taken place between the two previous census periods. On the other hand, the number of medical men regarded as in practice at the middle of each year is the arithmetic mean between the number of medical men shown by the *Medical Directory* to be resident in England and Wales in the issue for one year and in the issue for that which follows it. This seems the only possible method of making the calculation, and for all practical purposes may be taken as perfectly correct. The *Medical Directory* always includes a certain number of men who give up practice before the middle of the year, but a certain number who are not in practice when the *Directory* is published have commenced work by the time the sixth month has been reached, and the two may be balanced one against the other. Finally, in calculating the number of possible patients to each medical man, the medical population has been deducted from the total population.

In looking at this table the first notable point is that this period of twenty-eight years has seen a great increase both in the general population and in the medical population, but that relatively the increase in the latter is the more marked. In round numbers, the thousands of medical men have increased from 15 to 25; while, again, in round numbers, the millions of population have increased from 26 to 35. The percentages of increase from year to year are shown in the second and fifth columns respectively. On running the eye down these it will be seen that the rate of increase in the medical population, especially in the earlier years, is very irregular, while the yearly additions per cent. to the general population vary very slightly throughout the whole period.

This regularity in the case of the general population is, in a measure, artificial; for, though it is a fact that the population expands very steadily, the appearance of regularity is increased by the fashion in which the population is estimated, and by printing only few decimals. From this point of view, the figures given as regards the medical population may be regarded as the more correct, for they are founded on a yearly census as opposed to a ten-yearly census in the case of the general population.

For all practical purposes, however, both sets of figures may be taken as absolutely correct, and the point to be noted is that while the percentage of increase in the medical population varies from less than $\frac{1}{2}$ per cent. to over 3 per cent, the annual increase in the general population never reaches half that figure. It will be seen, too, that the higher figures in the medical population are all to be found in the first two-thirds of the period, while in the remaining one-third, or since 1898, there has been an intermittent tendency for the percentage of increase to diminish, such diminution for the last three years having been quite steady.

There still remains to be mentioned, however, the last column. This shows the number of possible patients which year by year each practitioner might have been expected to have, had the whole population been divided up in precise proportion to the number of medical men. It will be seen that each practitioner's field of work steadily diminished in size year after year until nine years ago, when it began slowly to expand once more. In other words, the number of possible patients to each actual medical man dropped from 1,710 in the year 1882 to as low as 1,384 in the year 1900, since when it has slowly increased until the ratio of possible patients to actual medical men—omitting decimals—now stands at 1,407 to 1.

All these points, however, will be gathered much more readily on reference to Chart B, opposite, and to Chart C, on p. 1434. These are graphs originally made on a very large scale, and in each case they are approximately accurate to three places of decimals. From Chart C will be gathered at a glance the fashion and extent to which each medical man's nominal field of action has expanded or contracted during the period under review.

The same knowledge could indirectly be gleaned from Chart B, but its real value is that it shows the different rate of increase in the general and medical populations much more clearly than the figures given in Table A. It should be noted that the percentages on which it is based are not the percentages given in that table. Those are the percentages of increase from year to year; while the percentages graphically shown in Chart B are the differences

between the first year under consideration and each of those which follow, and the chart makes it quite clear that almost throughout the period the increase in the number of the medical profession has been much more rapid than the increase in the population.

These tables, therefore, whether taken separately or together, conclusively prove that the second of the factors mentioned in the introduction has been actively at work in the last twenty-eight years. The supply has increased more rapidly than the demand, with the result that the ratio of possible patients to actual medical men has fallen by nearly 18 per cent. The first conclusion to be reached, therefore, is that, so far as factor No. 2 can decide the question, overstocking of the profession of medicine at present exists.

It would not be right, of course, to jump forthwith from this conclusion to a final verdict on the question initially raised, and to say that the profession of medicine has been proved to be a less efficient money-making machine for the average man than formerly. What has been proved so far is simply the existence of one circumstance which, unless counterpoised by some other circumstance, must inevitably bring about the condition of affairs in question. So far, in short, the evidence is of the kind known as *prima facie*, and it may even be that the relative overstocking is not really so high as that which the figures would indicate, because before the period commenced, as also throughout its first two-thirds, there was a large number of unqualified assistants at work as well as registered medical men.

This circumstance is not without interest, but for the moment it need merely be said that any effect it might be esteemed to have on the primary question under investigation is balanced by another circumstance, and that in any case the conclusion to be based on what is herein called factor No. 2 is not vitiated by its existence. The relative overstocking may be small or may be great, but in either case it represents a circumstance likely to diminish the financial attractions of medicine for the average man, for if a practitioner has even one more competitor to deal with than formerly, his chances of financial success are diminished to that extent.

The net conclusion, therefore, is that the investigation, even when carried out to this limited extent, has already revealed a circumstance which goes some way towards explaining and justifying complaints as to hard times amongst medical men.

SOME SIDE ISSUES.

Before ending this purely statistical consideration of a question which is as intricate as it is interesting, one or two comments may be permitted on the character of the curves in Chart B, and the cause of the fluctuations in the number of possible patients to each actual medical man shown in figures in Table A and graphically in Chart C.

As for the former, it is important to note that the disproportion in the growths of the two populations is evident at the very beginning of the period, and that, with one or two exceptional years towards the end, it is persistent throughout it. If, therefore, a cause is to be looked for, search must be made for a circumstance capable of continuous action, or for a sequence of circumstances whose net effect would be that in question. Nothing of the latter class suggests itself, but conceivably it might be argued that the growth of the medical profession is only abnormal because the general population has ceased to increase at the same rate as formerly, or because opportunities for medical men to settle abroad have diminished, or because medical men from the sister countries have settled down in England and Wales more frequently than heretofore.

On these points it need merely be said that the first contention would be annihilated by figures which need not here be given. The growth in the general population has by no means fallen off, while that of the medical population, so far as materials for calculation exist, has in the period under consideration vastly exceeded that of any earlier date.

As for the second suggestion, the cause in question may possibly have been at work, but it does not seem, on the whole, as if its effect could have been more than minimal. The third suggestion is insusceptible of statistical treatment, but the medical profession in England and Wales

CHART B.—Showing the Respective Growths of the Medical and General Populations during the Past Twenty-eight Years. The Upper Curve relates to the Medical Population.

has from the earliest times been largely recruited from Scottish and Irish practitioners, and the extent to which such recruiting has been going on during the past twenty-

eight years has not, so far as can be discovered, varied during the course of that period. It is true that the number of Irish medical graduates who remain in Ireland

has greatly diminished during the course of those years, but, on the other hand, the number of Scottish medical men who practise in Scotland has greatly increased.

On these grounds, therefore, it seems fair to conclude that the increasing gap between the curves in Chart B—the decreasing ratio between possible patients and actual medical men shown in Chart C—is due neither to an arrest of growth in the number of possible patients, nor to blockage of former outlets, nor to a mere transfer of medical men from one part of the country to another, such as would be represented by an influx into England and Wales of graduates from the sister countries.

The character of the curves is, therefore, in all probability simply due to the fact that too many men have entered the medical profession in the last twenty-eight years; either because owing to the spread of general education an increased number of men is seeking to enter the learned professions, and amongst others that of medicine, or because erroneous ideas have been prevalent as to the prospects which the profession of medicine offers.

There are two other points worth mentioning. The

action of the General Medical Council in putting a stop to the employment of unqualified assistants might possibly have been expected to affect the curve relating to medical men. Were it to be supposed that the unqualified man was capable of getting qualified, the effect of forcing him to do so or to abandon his occupation would seem likely to have increased the disproportion in the growth of qualified medical men. But, of course, the unqualified assistant was only unqualified owing to lack either of means or of energy to become qualified.

Quite naturally, therefore, his disappearance is not found to affect the curve in the manner stated. On the contrary, it is after his disappearance that the two curves tend to separate less widely. In other words, the disproportion in the growths of the two populations is less marked in the very latest years than in any part of the period, and this is why a slight rise in the number of possible patients to actual medical men is to be noted on Chart C. As already stated, the number at first ran down from 1,710 in the year 1882 to 1,381 in the year 1901, and then rose slightly until it now stands at 1,407.

CHART C.—Showing the Variations in the Number of Possible Patients to Actual Medical Men during the last Twenty-eight Years.

Why there should have been this slight rise is puzzling, and at present nothing which seems quite a satisfactory explanation suggests itself. It may be noted, however, that in the year 1890 the nominal length of the curriculum for medical students was extended, and it is about ten years later—by which time knowledge of the increased length must have become general—that we find the disproportion in the growths of the two populations slightly lessening. How long this diminution will continue remains to be seen. Meantime, the net outcome of the investigation represented by this article may be restated in a few words:

1. It has been found that the ratio of possible patients to actual medical men has materially fallen in the past twenty-eight years.

2. This means that one of the accepted causes of relative overstocking in any calling, trade, or profession, exists in the case of the profession of medicine.

3. Hence one specific factor has been discovered which quite independently of any other circumstance would go far towards explaining and justifying complaints of hard times among medical men.

4. Since the average medical man of to-day has even in point of mere numbers more competition to contend with than had his predecessor, it at once becomes evident that the profession of medicine should be regarded—*prima facie* at any rate—as a less efficient money-making machine for the average man than it was at the commencement of the period under investigation—namely, the twenty-eight years ending January 31st, 1909.

And this was the question initially propounded for consideration.

LITERARY NOTES.

SIR SAMUEL WILKS writes:

I have enjoyed reading about an old diploma, as the names of the signatories are familiar to me. On my own College diploma, 1847 (?), I have the name of John Goldwyer Andrews and also Liston. I forget the others, but I will try and find my diploma. Andrews I had seen and heard about, for my old master to whom I was apprenticed was dresser to him. He always called him in for consultation. He knew he was an uncultivated man, for he told the story of a student who, seeing lice on a patient's head, pointed them out to another student to warn him, said in an unknown (to the patient) tongue to his fellow, "*Pediculi!*" whereat the surgeon, also looking, exclaimed, "I see nothing particular" (*pediculi*). He mentioned also Andrews's jealousy on seeing his juniors performing new operations. These younger men were Adams, Scott, and Luke. I think it was the last who was the first man in London to remove the upper jaw for a growth. When half way through it he got into some muddle, and asked Andrews a question. He answered in a surly manner some words I forget, but equivalent to, "As you have attempted it you know best how to go on with it." Scott I knew by sight, as I often saw him riding home on horseback through Sydenham Park, and I am under the impression that it was his park which he sold to the Crystal Palace and on which it stands now. He had a large practice in the City for sore legs, because his father had commenced making sore legs a speciality and treating them in a manner which had a name like Baynton. The mercurial ointment he used was long after called Scott's ointment. I think it was nothing more than leaving off all the rubbish hitherto used, putting on some of this mild ointment, strapping it up, and leaving it alone for a week or two. This reminds me, after speaking of Liston, of University College, known for his splendid operations like Ferguson, that I think it was he who introduced water dressings for wounds, which I take it was mainly successful in preventing the use of the messes then in vogue. I was able to compare this superior method myself with what was done at the French hospital when I was in Paris, seeing the surgeon stuff in the charpie into a wound covered with some yellow stuff looking like the material they used to put into the axle-boxes of the railway carriages.

An article on William Hamilton, Royal Academician, fashionable portrait painter and friend of Mrs. Siddons, which appeared just a year ago in the *Connoisseur*, has a melancholy interest, as the death of the writer, Mr. A. P. Spanton, M.A. Cantab., LL.B., C.S. Ed., a son of Mr. W. D. Spanton of Stoke-on-Trent, was lately announced in the *JOURNAL*. Apart from the authorship the article has a distinct value of its own, as in it is given an excellent critical estimate of a British painter, now almost forgotten except by the few. According to Mr. Spanton, Hamilton may be regarded as one of the most successful pioneers of the English water-colour school, a fact which would have been recognized earlier if he had not died so soon. Many of his works are now lost, including some of his best oil paintings, but a sufficient number of water-colours remain to show his characteristics, and the difference in style between his earlier and his later work. All his best drawings, such as his "Shepherd Boy," "Girl with Cows," "Eve and the Serpent," belong to the later period, and were produced during the last six years of his life. His earlier work was done chiefly for book illustrations; for instance, he illustrated Tomkins's edition of Thomson's *Seasons*, which was published in 1797, and Macklin's Bible, published in 1800. The majority of his drawings were engraved by Bartolozzi. Hamilton did not disdain to try his hand at decoration, and a cabinet belonging to Charles IV of Spain and a state carriage of Lord Fitzgibbon, both adorned by paintings of his, still exist to prove the versatility of his art. He also painted a set of furniture in imitation of antique cameos for William Beckford, of Fonthill Abbey, the famous and eccentric author of *Vathek*, described in *Childe Harold* as "England's wealthiest son," and some arabesque decorations for the Marquis of Dute at Highcliffe, Hampshire. Of these, however, all trace has been lost. Hamilton's poetical and classical pieces, whilst resembling the work of his contemporaries Opie, Wheatley, and Kauffmann, seem to express more of the extravagance of the eighteenth century, and from them can be gathered a very good idea of the fashion in art at that period. Mr. Spanton's article is illustrated by reproductions of five of Hamilton's pictures, and the author has appended a list of fifty-nine of his extant drawings and paintings, with a full description of each.

In a thesis for the degree of Doctor of Medicine presented to the University of Paris on February 25th, M. Falin discusses the practice of medicine and pharmacy in ancient Rome. Greece had schools of medicine, but neither degrees nor diplomas. Roman medicine was altogether a Greek importation. Neither under the Republic nor under the Empire was there any diploma. In the Code of Justinian medical practitioners in whatever way they were connected with the treatment of the sick were called *Medici*, the art of pharmacy in the modern sense being in the same hands as the practice of healing. Cujas says: "*Medici sunt hi qui medicamenta conferunt, vulnera curant, cucurbitas admovent, item qui circumcidunt aut castrant.*" Although there was no diploma, those who wished to call themselves *medici* probably had to follow the lessons of a master with whom they visited patients; there was, in fact, a system of apprenticeship. For a long time pharmacy was a part of medicine, the doctors preparing their own drugs. Galen himself, who lived in the same century, kept an open shop on the *Via Sacra*. The doctors' shops contained not only drugs but dressings and everything necessary for medical treatment. That some of these drugs were poisonous may be gathered from the lines of Plautus: "*Cur ego vivo? Cur non morior? Quid mihi est in vita boni? Certum est; ibo ad medicum atque me ibi toxicum mori dabo.*" This reminds us of Astley Cooper declining to take elaterium from his physicians on the ground that he wished to die a natural death; or perhaps it may be taken to mean that the practitioners of that day were not unwilling—for a consideration—to provide their customers with the means of shuffling off this mortal coil. In the second century the practice of physic began to be separated from the preparation of remedies. The druggists proper at that time were called *Seplasiarii*, and dwelt in a quarter not far from the Capitol, called *vicus theurarius* or *unguentarius*. Even in those days there appears to have been a good deal of counter-practice, but as at present the chemist was mainly the doctor of the poor.

A NEW INSTITUTE OF PHYSIOLOGY IN LONDON.

ON Friday, June 18th, the new Institute of Physiology at University College, Gower Street, will be opened by the Secretary of State for War, the Right Hon. R. B. Haldane, K.C., M.P., F.R.S. Although at first sight there might not seem to be much in common between the position which Mr. Haldane holds in the Government and the part he is to take in opening an institute of physiology, there is a special fitness in his officiating at the ceremony. He is a man of wide and varied intellectual interests, with a thorough appreciation of the importance of science to the welfare of the nation as well as of the individual, and his family associations must tend to arouse in him a particular interest in physiology. His brother, Dr. John Scott Haldane, of Oxford, is recognized as a leading physiologist, while the late Sir John Burdon-Sanderson was his uncle. Moreover, the opening of the new institute is to be made the occasion of a review of the University Contingent of the Officers' Training Corps of the Territorial Force which Mr. Haldane has called into being; this corps owes much of its present state of efficiency to the patriotic efforts of Professor Starling and the other professors, all of whom are enthusiastic in the cause.

University College may be said to be the cradle of modern physiology in this country. There William Sharpey taught for nearly forty years. Before his time physiology was looked upon as a "poor relation" of anatomy, and was treated as of comparatively little importance. The teaching was directed mainly to meet the requirements of the College of Surgeons, and the College, though particular about bones and muscles, was believed to care little about cells and the functions of organs. Physiology, as Russell Reynolds said in an address delivered in 1858, was "thrown in as a makeweight." To Sharpey's teaching it was mainly due that physiology gained its rightful place in medical education, and, directly or indirectly, he trained most British teachers of that science for many years. It was at University College that the practical teaching of physiology begun by Michael Foster was further developed by Burdon-Sanderson. These great men were afterwards the creators of the schools of physiology at Oxford and Cambridge. The foundation of a new Institute of Physiology carries on the tradition of University College, and gives to the teaching of physiology there vastly increased possibilities of development.

University College and London University.

Before going further, a few words of explanation as to the existing relations between University College and the University of London may not be out of place, as there is still a good deal of confusion on the subject in the minds of many people. Till two years ago University College was an independent institution, governed by a Council which was elected at an annual meeting of the Board of Governors. In the hands of the Council lay the whole administrative control of the college. University College was in the same position in relation to the University as the London Medical Schools, Bedford College and other institutions, which are labelled "schools" of the university, but are practically autonomous. Of course the fact that University College had been in the first instance founded as "the University of London," and had, with King's College, for many years been the only institution within the University, gave University College a prestige not possessed—except in the case of medicine—to an equal extent by other places of education. But this was a matter more of tradition and staff than of legal status.

By the Act of Incorporation this independence of the college was abolished, and the hospital and that part of the medical school dealing with clinical studies and pathology were formed into a separate corporation, which, as a school of the university, bears the same relation as the other medical schools of London to the university. The whole of the rest of the college, including the departments for preliminary and early medical studies, was handed over to the university, which thus acquired, by the Act of Incorporation, complete control over the college. The college is no longer governed by an independent council but by the senate of the university, which entrusts

the actual administrative care of the college buildings and of the teaching carried on therein to a committee which it appoints.

This Act of Incorporation, the promotion of which in itself called for the display of some courage as well as devotion to the university ideal on the part of the authorities of the college, may be the first step in a great movement that will in time place the whole of the academic training in Arts, Science, and Engineering, under the direct control of the university. King's College, with the exception of the hospital and its departments dealing with clinical studies, will shortly be incorporated, and one of the main reasons for the appointment of a Royal Commission on the university was the necessity of bringing about some closer connexion between the new Imperial College of Sciences and Technology, and the university. By such an incorporation of the main bodies of academic studies in the university, an immense impetus will be given to the possibilities of consolidation and development of the facilities for higher teaching and research in London.

At the present time, a medical student who enters the University of London at University College or King's College, is in very much the same position as a student beginning his career at Oxford or Cambridge. He will pursue his studies in the sciences preliminary and ancillary to medicine in laboratories built and maintained by the university and staffed by men who are appointed by the university. In his studies he will have the advantage of mingling with students of other faculties—a condition which has always been regarded as an important factor in the general culture which a student is expected to obtain during his university career. At the conclusion of his training in anatomy, physiology, and pharmacology he will be free to make his choice of a hospital school at which to pursue his strictly professional studies in association with actual bedside observation. Some time must elapse before this condition of things will be extended to the whole of London; but revolutionary changes are so apt to be associated with the destruction of useful energy and material that the wisest course is to proceed gradually, especially in London, so that it may be seen how much of the existing structure can be worked into the university fabric and utilized as active parts of the academic machine. But the erection of such an institute as that at University College shows that the university is determined to take the lead in the development of higher education in London, and to be ready, when the time comes, for the consolidation of all higher scientific teaching under its own control.

Description of the Institute.

A short time ago a representative of the *BRITISH MEDICAL JOURNAL* visited the new institute, where he was most courteously received by Professor Starling, Dr. W. M. Bayliss, the Assistant Professor of Physiology, Dr. Page May, Lecturer on the Physiology of the Nervous System, and Dr. R. H. Aders Plimmer, Lecturer on Physiological Chemistry. By these gentlemen he was conducted all over the building. Though not yet complete in all its internal details, our representative was struck by the ample accommodation and the completeness, and indeed the luxury, of the equipment both for teaching and research. He mentally compared it with the laboratory of the early and middle Seventies, in which, according to the legend, Burdon-Sanderson was one day left by his assistant studying a frog's heart, with a sandwich beside him; on the return of the assistant he found the professor wrapt in contemplation of the sandwich, while the frog had disappeared. The difference between the two or three scantily equipped rooms of that day and the palace of science which is about to be opened may be taken as a visible proof of the progress of physiology during the last thirty-five years. For completeness of equipment there is, we believe, nothing to equal the new institute in Germany. A feature of the institute to which our representative gave special attention is the provision made for the comfort of the animals used for experiment. The sheds where they are kept are airy and at the same time well heated. The operating room is fitted up with the same elaborate precautions against sepsis—which means suffering—as those in hospitals of the most modern type, while the arrangements for their accommodation after operation gives proof of the most careful regard for their comfort.

BASEMENT.
SCALE OF FEET.

GROUND PLAN.

The architect is Professor Simpson, F.R.I.B.A., whose account of the buildings, kindly placed at our disposal, is virtually reproduced here. For the photographs we are indebted to Dr. May, to whom, as to Professor Starling, Dr. Bayliss, and Dr. Plimmer, we take this opportunity of expressing our gratitude for the trouble they have taken on our behalf.

The removal of University College School to Hampstead, which was made necessary by the incorporation of the college in the University of London, made available for university purposes not only the South Wing of the college which had been previously occupied by the school, but also a plot of land of 1½ acres in extent which had formerly been used as a playground. Almost every department in the college required increased space for its work. The pressing needs of the departments of chemistry and of the medical sciences, especially

Simpson in preparing plans for an institute of anatomy, physiology, and pharmacology, with a view to the immediate erection of a portion thereof for the department of physiology, at a cost not exceeding £15,000 without equipment. For the cost of equipment, estimated at £5,000, provision was subsequently made partly by subscriptions, partly by a legacy left by the late Mr. Thomas Webb to the college for the purposes of research. The work of building commenced in the first week of March, 1903, and was completed by May 1st, 1909.

Since the Institute of Physiology is to be part of an institute that will include the other medical sciences, it is so arranged that it can be extended in either direction according to the funds and the land which may be available. It is a simple rectangular edifice occupying a site 44 ft. by 144 ft. This runs east and west parallel to the south wall of the playground and also to the south

Fig. 1.—Main Entrance, facing due North.

physiology, could not adequately be met by a reconstruction of the South Wing, and it was agreed that for each of these departments a new building was necessary. It was estimated that the cost of such an institute of the early medical sciences would be £50,000, namely, £20,000 for anatomy, £20,000 for physiology, and £10,000 for pharmacology. To meet this expenditure the only money available was £10,000, which had been included in the money raised for the provision of the increased accommodation necessary by incorporation, but on July 11th, shortly before the vacation of the ground by the boys' school, two sums, one of £2,000, the other of £3,000, were offered by Dr. Aders Plimmer and Dr. Ludwig Mond for the purposes of a physiology building on condition that the £10,000 already available was also devoted to this purpose and that the erection of the building be commenced forthwith. These offers were accepted by the Senate of the University, and a committee was appointed to co-operate with Professor

wing of the college, from which it is distant about 90 ft. Its west end approaches closely to the walls of the gardens of the houses in Gower Street, space thus being left at the east end between it and the racquet court for the erection at an early date of the pharmacological laboratory. Since the building does not front on the main street, architectural embellishment has been diminished as far as possible, the sole objects aimed at being simplicity of construction, stability, and light. Nevertheless, the front is striking from its size and justness of proportion. (Fig. 1.)

The building consists of a central vestibule and staircase, which is approached from the playground by two flights of stone steps. Underneath this vestibule is a tunnel through the building giving access for carts from the mews in Francis Street. Above the basement are three floors, which consist, practically of six large rooms, each measuring about 62 ft. by 41 ft., divided into smaller rooms by means of partitions. Thus, at any future time

it will be possible at very small expense entirely to rearrange the rooms on any floor to meet whatever requirements may arise.

Certain features are to be found throughout the building. The windows, which occupy the maximum amount of wall space allowed under the Building Act, have wide casements opening inwards so that they can be cleaned at any time from the room. Above these casements is a sash hinged vertically for ventilation. The window-sills are as nearly as possible on a level with the window benches, so that no shadow is cast by the sill on the table. All rooms are amply supplied with water, gas, and electric leads. The main water supply is derived from a 3-in. pipe which comes off the main, and is carried up in the centre of the building to the roof level. From this main pipes are taken off at each floor to supply the various benches and sinks. In addition, there is a so-called high-pressure supply, which runs direct from the main to the taps, to which are going to be attached filter pumps or water motors. At the top of the building are two large cisterns with a capacity of 2,000 gallons, which serve as a supply for the boilers as well as a reserve for the whole building in case the water is at any time turned off at the main. By means of valves it is arranged that

the whole water supply of the building is automatically connected with the tanks whenever the pressure in the main drops below a certain point.

Most of the rooms are also supplied with gas from two sources, each of which can be controlled from the basement. One of these is constant for the supply of incubators, etc.; the other is turned off every evening at the main. Hot water is also supplied to the chief laboratories. Care has been taken that

none of the pipes shall run in inaccessible positions. They either run freely on the walls or in special canals in the floor which are covered with iron plates, so that access is easy at any time. All the pipes are painted, of different colours according to the purpose they serve—for example, constant gas is yellow, ordinary gas red, hot water aluminium, etc. It is possible to turn off both gas and water at every working place from every bench, from every floor, as well as for the whole building.

The heating of the building is effected by means of low pressure steam radiators on the Webster system. In most cases the radiators are situated under the windows, and an air inlet is provided in the wall so that the air may be warmed as it enters. For the extraction of the vitiated air, the theatre, the main class rooms, as well as the dark rooms, are connected by flues with a large extract flue in the roof, from which the air is extracted by means of a sirocco fan driven by a 5-h.p. electric motor. Since the main extract flues are provided with shutters, as are also the flue openings in the various rooms, it is possible to direct the whole force of the extract draught to any particular room. Thus it is possible to provide a current of 12,000 cub. ft. a minute through the theatre or through either of the large class rooms in case of necessity.

The main entrance, which is on the ground floor, is

approached by a double flight of steps from the playground. From the landing at the top of the steps one enters the vestibule, which is separated by a glass screen with swing doors from the inner vestibule, which gives access to the laboratories on each side of the ground floor as well as to the main staircase. Into the inner vestibule also opens the lift.

The staircase is built round a well at the back of the building. It is well lighted by windows at the south side as well as by the top light in the roof. The stairs, as well as the doors of the vestibule, are made of oak. The walls of the staircase have a dado 4 ft. high of a greenish terrazzo with a fillet of oak. All the other walls in the building, with the exception of those in the aseptic department, are distempered.

Physiological Chemistry.

The ground floor is devoted entirely to physiological chemistry. To the right of the entrance—that is to say, on the west side—is a large students' laboratory about 62 by 40 ft. (Fig. 2). It is lighted by six windows on each side, and is fitted with twelve benches, each of which will accommodate eight students. Each bench is 12 ft. long by 4 ft. 6 in. wide. The floor of the laboratory is covered with wood planking, except under each bench, where a

cement platform is provided at a level $\frac{1}{2}$ in. above that of the surrounding floor, so that the bench rests on cement, and any water which may accumulate below the benches will at once run away. The water and gas are brought to the benches by pipes lying in a channel in the floor to which access is easy, and are distributed to the benches without being hidden anywhere in their structure. The waste from the benches is carried into open glazed

Fig. 2.—Students' Laboratory of Physiological Chemistry.

earthenware channels resting at the outer ends of the benches, and opening without traps into lead heads outside the building. The channels are rendered in cement and the earthenware pipes set in bitumen. They are closed by iron plates, which can be raised for inspection at any time.

In three of the windows on each side of the room (six in all) are placed double fume cupboards, so that all manipulations in these cupboards are carried out in the best possible light. Each cupboard is provided with two extract flues built into the wall, and forming rectangular earthenware pipes glazed internally, which terminate on the roof in special heads to prevent any down draught. Even under ordinary circumstances there is usually a very good draught up each of these flues, but each is provided with a gas burner so as to ensure the absence of any down draught.

On the south side of the building the westernmost window opens at the floor level on to a stone balcony which is provided with a stone shelf, with a glazed sink, water and gas. The balcony is roofed in by glass, but is open at the back and sides so that it is possible to carry out manipulations involving the production of objectionable fumes practically in the open air. Between the fume cupboards seven large wooden tubs are provided for

washing-up purposes. Each of these has a large draining rack immediately above. The four benches at the west end of the room have plugs connected with a special electric heating circuit, so that it may be possible to heat inflammable liquids without the use of any flame. The benches are of a pitch pine framing with teaktops; their general structure will be evident on reference to the figure.

The east side of the ground floor is devoted to laboratories for research in physiological chemistry. There is (1) *A Balance Room* with teak shelves for four balances, each provided with an electric bracket at a suitable distance over the balance. The floor is of linoleum over cement. Next to this room is (2) the *Private Laboratory of the*

Assistant Professor in charge of the department of physiological chemistry. This room, about 20 ft. by 22 ft., has two double benches, each with gas, ordinary and high pressure water supply, and electric heaters. The pattern of these benches varies slightly from that adopted in the

students' room in order to give greater variety in the shape and dimensions of the drawers and cupboards. There is a small sink at each end, each with a three-way tap and a high-pressure tap for filter pumps, and in the middle of the bench four water-taps over a central glazed earthenware channel for use in distillations, etc. All washing up is carried out at a large wooden tub between the windows on the north side of the room. There are two fume cupboards, namely, a large one in one of the windows and a smaller one against the west wall. Along the rest of this wall is a lead covered bench fitted with water and gas for miscellaneous operations.

A door leads from this room into the *General Research*

Laboratory. This is a large square room about 25 ft. by 25 ft., also provided with two double benches each 12 ft. long, 4 ft. 6 in. wide, to accommodate eight workers. This room, like the private laboratory, has two fume cupboards, one in the window and one against the wall, and a lead

covered bench with water and gas. In addition to the draining pegs over the two washing tubs, each worker is provided with a small draining rack, which is hung at the side of his working place. On this are placed his glass apparatus, after using at the end of each day, so that it shall be ready for his use the next morning. Both these laboratories have a copious supply of hot water for washing purposes. The floor is of deal boards. The supply pipes are brought to

the benches in floor channels, and wastes are carried in glazed earthenware channels, as in the large students' laboratory.

Opening out of the south side of this room are the combustion room and the distillation room.

The *Combustion Room* is provided at each side with a stone bench 3 ft. above the ground, 2 ft. wide, each with a stoneware sink 2 ft. 6 in. by 1 ft. 6 in. by 9 in., arranged so as to take two aspirators from gas reservoirs. The bench is set on glazed brick piers, and is supplied with large gas nozzles for combustion furnace. One of the bays below the bench on the east side is closed by a wrought iron sliding door, and is used for working with the tube furnace. Over

each bench is a wooden hood lined with malite, which conducts the gas fumes into a flue running directly to the top of the building. The floor is of cement.

The *Distillation Room* is provided on each wall with a lead covered bench with water and gas supply. The high

Fig. 3.—Research Laboratory of Experimental Physiology.

Fig. 4.—Laboratory for Physical Measurements (Dr. Bayliss).

pressure supply is also carried to a sink near the window to allow for vacuum distillations. In this room we also find electric leads for supplying heaters. The floor is of asphalt on cement. On one wall is fitted a range of drying ovens combined with an apparatus for the production of distilled water. The window of this room, which opens down to the ground, leads on to a stone balcony for work involving the production of objectionable fumes, similar in all respects to that provided in the students' laboratory.

There is a small room for use as a private office by the head of the department.

Adjacent to it is the *Gas and Optical Room*, that is, a room where operations may be carried out involving the use of mercury or the use of instruments which cannot be exposed to the ordinary fumes of a laboratory.

The last room in this side, which adjoins the inner vestibule, is a small room with double doors which can be completely darkened for polarimetric work. The bench is fitted at one end with a small hood leading into an extrac flue, so as to conduct away at once the fumes given off by the sodium chloride lamps which are ordinarily so destructive for all brass apparatus. This room is also fitted with small taps connected with a hot and cold water supply, so as to be able to lead a current of water at any desired temperature through or round any instrument where variations of temperature are desired. These three rooms last mentioned have floors of linoleum over cement.

Experimental Physiology.

The first floor is devoted to experimental physiology on

the west side of the staircase, and mainly to the large theatre on the other.

The *Theatre* is 50 ft. long by 40 ft. wide by 19 ft. high. It has seating accommodation for about 200 students. It is entered by the students by a branch staircase from the

first landing above the vestibule. The lecturer enters through a preparation room, which communicates on the other side with the professor's private room. The chief light to the theatre comes from three large windows on the north side, but light is also obtained from hemispherical windows placed high up on the south side. A passage 2 ft. wide is left between the benches and the north wall so as to allow of access from the building to be later

erected for pharmacology. From this building, too, it will be possible to provide for a students' entrance to the benches from the back of the theatre. At present the theatre suffers from the disadvantage that students entering late have to pass the lecturer's table in order to get to their places.

The windows are provided with light-tight blinds which can be raised or lowered in twenty seconds by means of an electric motor, and set into action by switches on the lecturer's table. The lighting is by incandescent lamps from the ceiling over the auditorium, an intense light being thrown on the back of the theatre as well as on the table by a row of 1,600 c.p. metallic filament lamps fixed immediately over the table. At the back of the lecturer

Fig. 5.—Students' Laboratory of H Stelgis.

Fig. 6.—Demonstration Theatre.

turer are three tiers of slates arranged so as to slide up and down in sashes and providing altogether six blackboards, each 5 ft. by 3 ft. There is a space of 10 ft. clear between the back of the lecturer's bench and the wall, thus providing ample room for the display of apparatus. There are two

lanterns, one with a small arc lamp by the south end of the table for the projection of ordinary lantern slides, the other the large epidiascope of lights at the north end, which takes a current of 30 amperes, and by which it is possible to show lantern slides in broad daylight, or in the darkened theatre solid objects or microscopic specimens.

The rest of the wall is occupied by two large diagram screens, which can be rolled up out of sight when not in use, and are composed of lathes attached to webbing, to which diagrams can be pinned or clipped.

The space between the theatre and the central well of the building is taken up with a preparation room and with a spacious dark room.

Immediately in the middle of the building is the professor's private room.

The series of rooms on the west side of the first floor are known as the Thomas Webb Research Laboratories, to commemorate the legacy of £5,000 by Mr. Thomas Webb to the college for the purpose of research, which was devoted in accordance with his wish to the expenses of the physiology building.

On the north side are three rooms. Immediately opening out of the professor's private room is:

The *Departmental Library*, with shelving for about 4,000 volumes, where will be kept (at any rate until the completion of the whole Institute of Medical Sciences) the periodicals and works in the College Library dealing with physiology and cognate sciences. In the centre of this room is a long table on which are arranged the current numbers of the physiological periodicals.

Adjoining the library is the *Professor's Private*

Laboratory, a room about 20 ft. by 20 ft., fitted with shafting and electric power and with a chemical bench along one side. Opening out of this, but approached also from the central corridor, is the *General Research Laboratory* (Fig. 3), 25 ft. by 25 ft., also fitted with shafting and

motive power, a chemical bench, and a fume cupboard. In this room are two kymographs.

On the south side of this wing are three rooms, namely, one fitted out for accurate physical observations, and occupied at present by Dr. Bayliss (Fig. 4); a large room which can be completely darkened for optical experiments or for investigations involving the use of mercurial gas pumps; and a small workshop fitted with lathe and bench. The

mezzanine floor between the first and second floors provides a cloak room for the ladies who are working in the laboratory, a lavatory and bath room for the staff, and a small room known as the committee room.

Histology and Neurology.

The second floor is devoted to the departments of histology, of neurology, and to the aseptic department. The whole of the west wing of this floor is taken up with a large students' classroom for histology and experimental physiology. This room (Fig. 5) is about 63 ft. by 42 ft., its height varying from 14 ft. at the sides to 20 ft. in the middle. It is brilliantly lighted by large windows at both sides, and by a continuous sky-

light along the whole of the north side of the room. It is fitted with working benches providing seventy places for students of histology. Each student is provided with a locker and drawer, with water, gas, and electric light. In addition there are five tables, each 8 ft. 6 in. by 2 ft. 6 in.

Fig. 7.—Aseptic Department: Operating Room.

Fig. 8.—Aseptic Department: Animals' Hospital.

fitted up with shafting for experimental physiology. Three of the histology benches are also provided with continuous shafting, and space is left in the room for additional benches, which would provide another thirty-two places. The walls of this laboratory, as of the big chemical laboratory downstairs, are of glazed brick.

Adjoining this room, on the north side, is a preparation room for the teacher in charge of the histological students.

On the south side of this floor are the following rooms:

At the north side there is a *Demonstration Theatre* (Fig. 6). Here the benches, which present only standing room, rise rapidly in semicircular tiers, and are so arranged that forty students can obtain a full view of any experiment. This room is provided with a kymograph, artificial respiration, time mark, etc., with water and electric power, and is brilliantly lighted by windows as well as by the skylight. The rest of the rooms on this floor are devoted to research.

Adjacent to the demonstration theatre is a well-lighted room fitted up for histological research.

Opposite these rooms on the south side is the department devoted to the physiology of the nervous system. This includes three rooms: one for keeping monkeys; a large room fitted with benches, incubators, etc., for histological work; and a small room with skylight which can be used by the lecturer in charge of this branch of the subject.

Aseptic Department.

The east end of this wing, separated from the rest by a door in the passage, is devoted to the aseptic department. This includes four rooms. On the north side is a sterilization room, provided with a Manlove and Alliott steam sterilizer, and the necessary arrangements for the sterilization of instruments and the preparation of animals for operation (Fig. 7). There is also an operating room, provided with double windows so as to make the attainment of a high temperature possible. Instead of the ordinary radiators, the heating of the room is effected by means of nickel-plated copper tubes which run in loops round the walls at such a distance from one another that all accumulation of dust can be prevented. There is a wash-basin provided with hot and cold water supply, a glass shelf for antiseptic solutions, and a slate shelf with gas, at which a plentiful supply of warm sterilized normal salt solution can be provided. All the supply and waste pipes are taken straight out of the room through the wall, so as to avoid any chances for the accumulation of dust. The floor of this room, as of all the other rooms in the aseptic department, is of terrazzo, and the walls and ceilings are of adamant painted with ripolin enamel.

Between this room and the passage is a *Bath Room* for the preparation of animals.

On the south side of the passage is the *Animal Hospital* (Fig. 8), excellently lighted and ventilated, provided with four kennels carried out in glazed brick for dogs, and with ample space for cages for other animals.

Both this and the adjoining Monkey Room are provided, in addition to the steam heating apparatus, with gas stoves, which can be lit in the evening, so as to prevent any falling of temperature during the night.

Refrigerating Chambers, Machinery, etc.

On the west side of the basement are a series of rooms which can be regarded as serving all departments of the building. Both sides of the basement are only just below ground level, so that they are excellently lighted. On the north side, next to the central roadway, is the *Refrigerating Chamber*, with thick brick walls in which is built up the chamber proper—two layers of wood, with a packing of slag wool between. A space is provided for cold storage, about 6 ft. 6 in. by 10 ft. by 7 ft. 6 in. The chamber is lined throughout with zinc, so that it can be effectively disinfected, and is provided with an air-lock so as to diminish the access of warmth when it is necessary to enter or leave it. It is provided with large accumulative tanks containing calcium chloride solution, so that it may be possible to limit the running of the refrigerator to two or three hours daily.

Next to the refrigerating chamber is the *Machinery Room* containing the refrigerating machine, driven by a 5-h.p. electric motor. The counter-shaft of the motor is prolonged and geared on to two other sets of shafting, so that it is possible to obtain a large range of speeds for driving other apparatus such as centrifuges, grinding mills, etc. In this room are also contained the gas meter, the main tunnels and fuses of the electric supply, and the three switch-boards from which light, power, and heating circuits are carried to the different parts of the building.

The end room on this side, which is lined with glazed brick, forms a *Fabrik-Raum*—that is to say, a room for working up material on a large scale. It is fitted with sink with hot and cold water, a slop sink with flush cistern, a large fume cupboard with stone bench, and an apparatus for

Fig. 9.—Sheels for Animals.

the production of distilled water in quantity. The floor is of asphalt and is channelled so that the whole floor may be washed down with a pail of water, or the out-flow may be provided from a table in the middle of the room.

On the south side of the wing are the following rooms:

The *Boiler Room*, containing two low pressure steam boilers, the vacuum pump for the heating apparatus, worked by a 3-h.p. electric motor, and the hot water boiler with a storing capacity of 250 gallons. Opening out of this is the *Coal Cellar*, and enclosure with *Destructor Furnace*. The latter is one of Horsfall's destructors, fitted for gas.

There are two *Store Rooms*, one for apparatus the other for chemicals.

Adjoining the staircase is an *Incubator Chamber*. It has double brick walls with an air space between, the interior one being of glazed brick. It is provided with a gas stove and temperature regulator on Hearson's principle.

On the east side of the basement are the following:

A *Class Room*, fitted with platform, blackboard, and benches for small tutorial classes. From the west end of this room access is obtained to the enclosure containing the lift machinery. Opposite this room on the south side are a series of lavatories for workers in the department. The end room on the north side is devoted to Comparative

Physiology. There is a room for the servants of the institute.

There are two dark rooms for photomicrography, etc. One of these rooms is provided with a masonry pillar with slate top, so as to provide a support free as far as possible from any vibration.

Sheds for Animals.

In the yard on the south side of the building, and extending as far east as the racquet court, is a building about 12 ft. deep by 76 ft. long, containing accommodation for animals (Fig. 9). It is divided up into a number of rooms, namely: (1) Small laboratory; (2) store room for food; (3) dog kennels; (4) rabbit room; (5) room for animal cages; (6) a room, with stone bench and gas, for the preparation of the animals' food. In this room is also situated the heating apparatus—a gas stove which warms a run of hot-water piping passing through the different rooms. There is a yard in which cats and other animals can take exercise.

The opening of the new Institute of Physiology will mark an important date in the evolution of scientific teaching in this country, and we look with confidence to Professor Starling and his associates for results corresponding to the splendid opportunities of research now open to them.

MOTOR CARS FOR MEDICAL MEN.

COST OF RUNNING.

SWIFT AND SURE writes: As a user for over two years, may I stand up for the motor car in general and the little Swift in particular? For the man who values a little leisure in life over and above that spent in sleep, the motor is a veritable godsend, and surely he is prepared to pay a small sum for that sorely-needed commodity. Again, if he uses his car other than for his practice, he should be prepared to pay a little for that pleasure which is an extra.

To the general practitioner who tells me he runs 12,000 miles per annum in his practice, I cry, "Fudge." How many of us could stand cycling 40 miles a day? and yet most of us did our work upon the handy "bike" before taking to motors. My father and I have each of us cars with recorders, and I find that I average about 5,000 miles a year, and my father, who does about the hardest practice in this city, about 6,000 miles. As to tyres, I have all my original Dunlop tyres on the car, only two of them being retreaded, and this after 10,500 miles. My repair bill besides this has been confined to overhauling and renewal of brake bands. Most of the necessary work on a car can be done by any intelligent man who understands it. I have recently cleaned out my engine and ground in the valves in five hours. My car is running to-day almost as well as when I bought it, and if I bought another to-day it would be a "Swift."

The total expenses for last year, including garage, lighting, cleaning, warming, overhauling and some varnishing, insurance, oil and petrol—in fact, everything—totalled with me £78. Care and attention to one's car cuts down expenses out of all proportion to the time bestowed; and if doctors would read their cars as they do their patients, and relieve their little groans and squeaks, their repair bill—at any rate, in their early years—is practically negligible. Why, even my sparking plugs have been in for almost two years!

If the medical man wishes to economize on his car, let him get a two-seater with big tyres. It is the man who buys a large-bodied car and takes his family all over the country, driving on small tyres, who grumbles, and he forgets that his wear and tear is accomplished in the time which is not consumed in his practice, and the useless weight he carries around with him when it is.

MEDICAL BAG ON MOTOR CYCLE.

DR. Q. R. DARLING (Eardisley, Hereford) writes: In reply to "J. D.'s" query in the BRITISH MEDICAL JOURNAL, June 5th, p. 1365, after fifteen years as a medical cyclist, I can strongly recommend "Turner's Bi-carrier" on back of cycle, and Lucas's "Bundle Carrier" on handle bars. These will carry a large quantity of luggage and not be found to interfere with the riding, as a bag carried on the top bar.

STEAM CARS.

R. E. E. asks for notes of experience of the upkeep of steam cars, say Stanley 10 h.p., their advantages and disadvantages.

TOWN AND COUNTRY.

DR. AMPROSE ATKINSON (Green Lanes, Hornsey, N.), writing as a town doctor, emphatically advises any medical men contemplating changing from horse to motor not to do so. The motor for a general practitioner in a town is, he considers, a constant and serious source of anxiety. He offers to give any one thinking of making the change from horseflesh to motor the benefit of his pecuniary experience.

Medical News.

THE King has been pleased to grant permission to the undermentioned gentlemen to accept the decorations stated against their respective names which have been conferred upon them on the nomination of the Khedive of Egypt in recognition of valuable services rendered by them: Henry Pottinger Keatinge, Esq., M.B., F.R.C.S., Director of the School of Medicine and of the Hospital of Kasr-el-Aini, the Imperial Ottoman Order of the Medjidieh, Second Class; Frank Cole Madden, Esq., M.D., F.R.C.S., Professor at the same School of Medicine, the Order of the Medjidieh, Third Class.

DR. AENEAS JOHN McDONNELL, of Toowoomba, has been appointed a member of the Queensland Medical Board.

At a meeting of the Royal Microscopical Society, 20, Hanover Square, on Wednesday next, at 8 p.m., Dr. J. A. Braxton Hicks will give an exhibition of the better known tropical parasites.

THE honorary degree of LL.D. was conferred upon Professor C. S. Sherrington, Professor of Physiology in the University of Liverpool, at the graduation ceremonial of the University of Glasgow, on June 8th.

At the meeting of the Medical Society of the State of California, held recently at San José, Dr. James H. Parkinson, of Sacramento, was elected President for the ensuing year. Dr. Parkinson holds British qualifications, and is a member of the British Medical Association.

THE annual general meeting of the Society of Tropical Medicine and Hygiene will be held at the rooms of the Medical Society of London, Chandos Street, on Friday, June 18th, at 5 p.m. On the same evening Professor Ronald Ross, C.B., F.R.S., will take the chair at a dinner to be held at the Trocadero Restaurant.

THE Cavendish lecture will be delivered before the West London Medico-Chirurgical Society by Sir Victor Horsley, F.R.S., on Friday, June 25th, at 8 p.m., at the Kensington Town Hall. The subject of the lecture is the cerebellum. The society will hold its conversazione on the same evening.

AN extraordinary general meeting of the members of the London and Counties Medical Protection Society will be held on June 23rd, at 3.30 p.m., at the offices of the society, 31, Craven Street, Strand, W.C., for the purpose of considering certain alterations in the articles of association. The annual general meeting of the society will take place on the same day at 4 p.m. for the reception and adoption of the annual report and balance sheet and for the election of officers.

THE International Council of Nurses, founded in 1899, will hold a meeting on July 19th at the Caxton Hall, Westminster, to report progress and to receive reports from different countries upon questions relating to the welfare of the sick and of the nursing profession. Following the business meeting of the International Council an international congress of nurses and nursing exhibition will be held at Caxton Hall on July 20th, 21st, 22nd, and 23rd.

AN Conference of the National Federation of Hair-dressers, which was recently held at Scarborough, rules enjoining strict cleanliness on all working in barbers' shops were adopted. A special committee has been appointed to deal with all questions relating to "foul-shave" charges, "barber's rash" advertisements, and also to approach the British Medical Association with the view of inducing them to use the correct term of "tinea sycosis" instead of "barber's rash" or "foul shave."

THE sixth annual course on ophthalmology in connexion with the University of Oxford has been arranged from July 5th to July 17th. The main idea of the course is to demonstrate—on actual patients as far as possible—the whole range of ophthalmology in order to make the reading of a textbook more profitable than can be the case when relying merely on pictures. The first part will be mainly devoted to demonstrating the practical examination of eye patients, the use of the ophthalmoscope and the work of refraction. During the second part the work will be more specialized and the lectures delivered by various ophthalmic surgeons. Altogether some 500 cases will be available for demonstration. The fee for the course is £5 5s. Gentlemen attending it will be provided with board and residence at Keble College at the rate of 7s. 6d. a day during the second week, but during the first week lodgings must be secured. Further particulars may be obtained from Mr. Robert W. Doyne, M.A., Margaret Ogilvie Reader in Ophthalmology in the University of Oxford, 30, Cavendish Square, London, W.

British Medical Journal.

SATURDAY, JUNE 12TH, 1909.

THE MODERN TREATMENT OF FRACTURES.

THE address delivered at Cardiff by the President of the International Surgical Society, Dr. Lucas-Championnière, which we publish elsewhere, is important not only because of the occasion, but still more because of its subject and of its author. The occasion was noteworthy, seeing that it was that of the public expression of sympathy with Drs. Lynn Thomas and Skyrme by practically the whole of the medical profession in this country and by many distinguished foreign surgeons. It was at the same time a protest against the decisions of judges and juries, who have shown themselves quite incapable of understanding or appreciating the technical evidence given by a number of surgeons of the greatest skill and experience. The best thanks of the profession are due to Dr. Lucas-Championnière for once more testifying to the skill of our colleagues and to the brotherhood of surgeons of all nations. The matter of his address is of yet greater importance, and we trust that it may have the effect of arousing those British surgeons who have not already tried early massage and movement to the necessity of reconsidering their treatment of fractures.

For a generation Dr. Lucas-Championnière has been working at this subject, but he himself gives the year 1884 as that in which he first began the systematic treatment of fractures by massage and early mobilization. It needed no little courage to denounce the time-honoured methods of fixation, which have come down to us from before the dawn of history. Dr. Lucas-Championnière had to face a storm of criticism from some of the best surgeons of the day, but he met it without flinching, and in paper after paper read at the Paris Surgical Society and elsewhere he opposed facts and an ever-growing experience to *ex cathedra* statements of time-worn principles and *a priori* objections, until he won recognition for his methods. It is now not too much to claim that by early massage and mobilization the time of treatment of many fractures may be shortened by one-half; and, what is still more important, that the pain and disability which too often remain after so-called cures may be enormously lessened, especially in the case of fractures near to or involving joints, such as Colles's and Pott's fractures, to quote two of the commonest and most disabling of these injuries.

Dr. Lucas-Championnière, who was one of the earliest and most strenuous advocates of antiseptic surgery in France, paid a graceful tribute to Lord Lister's genius when he said that it was largely owing to his example as an innovator that he was led to question the time-honoured principles of immobilization. We fear that it may be somewhat disappointing

to our distinguished guest to find that comparatively few surgeons in this country have learnt the lessons which he has been teaching for more than thirty years. It should be some consolation to him to reflect that the teaching of our own great countryman was but slowly accepted by us, and that a new method of treatment coming from abroad is even less readily adopted, despite the proverb concerning the honour of a prophet in his own land. Dr. Lucas-Championnière's visit and address on such an occasion should go far to disturb the self-satisfaction which has been content with ancient ways, and it should stimulate the wider use of a method which has brought forth such good results in the hands of those who have given it a fair trial. Of the latter, Sir William Bennett, the latest edition of whose book is reviewed in this issue, is a notable example, one whose ripe experience and sound judgement ought to have great influence with the profession at large.

Stare super vias antiquas may be far easier than to leave the beaten track and explore new country; and it must be confessed that the old plan, which Professor G. Elliot Smith has shown was in use in Egypt some five thousand years ago, of "setting" a fracture, fixing it as firmly as possible in some apparatus and leaving it there till the time believed to be necessary for consolidation has passed makes fewer calls upon the attention and skill of the surgeon than does the treatment by massage, which needs constant supervision if it is to produce the best results. Those, however, who are willing to acquire such skill and to give such attention will be well repaid by the gratitude of their patients and the satisfaction of doing good work.

Dealing with another side of the question, Dr. Lucas-Championnière did well to insist upon the advisability of employing *x* rays in the course of the treatment of fractures; he did well also to point out the limitations of the method and the false conclusions to which it may lead inexperienced persons. He has himself published an essay on the errors of radiography, and in this country numerous papers on the subject have appeared in our columns and elsewhere, which show the many sources of error in the interpretation of plates and prints. Every surgeon, when called upon to treat a fracture, would do well to adopt the precaution, when possible, of having radiographs taken, not so much for his own guidance as for his protection against subsequent accusations by the patient or his friends. We say advisedly radiographs, for no one should be satisfied with less than two, taken if possible in planes at right angles to each other, for it is not uncommon to find that a plate taken from one point of view may represent perfect reduction, while one taken from another point may show both angular deformity and overlapping of bones.

Dr. Lucas-Championnière also very wisely insists that patients and their friends should not be invited to inspect the negatives, the unfamiliar appearances of which may lead to strange errors and consequent complaints of wrong treatment. It is the duty of the profession to educate the public to the extent that it shall know and admit its own unfitness to interpret radiographs, and at the same time to awaken it to a consciousness that the treatment of many fractures has of late years been radically reformed. The weighty utterance of the President of the International Surgical Society ought to give fresh impetus to our efforts in this direction, and we trust that by practising his methods British surgeons will show their appreciation of the graceful tribute of fraternal homage which, to use his own words, he has offered us.

THE MEDICAL TREATMENT OF SCHOOL CHILDREN.

ONE of the most important matters to be considered by the Annual Representative Meeting is the medical inspection of schools and the practical consequences that must logically follow on the adoption of that necessary addition to our system of State-aided education. The principle that all children in Board Schools should be medically inspected is excellent in itself, but the mere recognition of disease or physical defect does not take us very far. Provision has to be made for treatment, and here a serious difficulty meets the social reformer. Where and by whom are the children found on inspection to be diseased or defective to be dealt with? The first thought of the administrative authorities is to save expense, and therefore they—naturally from their point of view—look to the hospitals. For this the hospitals themselves are mainly responsible, for they have accustomed the public as well as the profession to believe that they gladly suffer all manner of patients to throng their out-patient departments, as they go to swell the number of attendances and thus help to make a good case for support in their periodical appeals to the charitable public. It was inevitable that this solution of the problem should not commend itself to the great mass of the medical profession in large towns, which already finds the hospital out-patient department a most damaging competitor in the struggle for existence.

As our readers know, the matter has received the closest attention from the Medico-Political Committee of the Association, and, as occasion arose, it has been dealt with in the JOURNAL. A report on the subject to the Divisions by the committee was published in the SUPPLEMENT of May 15th, and the recommendations are on the Agenda of the Representative Meeting (see SUPPLEMENT, May 22nd, p. 271). It may not be out of place to recall here the principal of these. Briefly, it is recommended that the Association should oppose the reference of such children to public medical charities for treatment; that there is no objection to treatment by provident dispensaries or other contract practice organizations, provided the practitioner who carries it out is adequately paid for his work; that the Association should oppose any scheme for treatment which involves reference of the children to the Poor Law pending such reforms as may result from the consideration of the reports of the Royal Commission. It is further recommended that, under existing conditions, the most satisfactory provision for the treatment of children whose parents cannot afford to pay for it, is to place them under the care of private practitioners, who should be adequately remunerated out of public funds independently of the Poor Law. In sparsely-populated districts, the committee recommends that the surgeries of private practitioners should be recognized as places where the children may be treated at the public expense; and that in towns the work should be entrusted to private practitioners, who should treat the children, either at convenient centres (designated "school clinics") situated in the schools or in independent buildings.

In London the question has become one of urgent importance, as the County Council has recently adopted provisionally a proposal made by its Education Committee to invite the hospitals to become in this respect a part of a State Medical Service. A Special Subcommittee appointed by the Education Committee, consisting of members of the London

County Council or of the Education Committee, and of experts and representatives of outside institutions, whose report was published in the BRITISH MEDICAL JOURNAL of December 26th, 1908, p. 1869, after full consideration of the subject recommended that, for children suffering from physical defects not requiring operative or in-patient treatment, the Council should establish school clinics at suitable centres in the metropolis. A Minority Report recommending that the Council should utilize for the purpose existing types of institutions, giving financial help, if necessary, and receiving special facilities in return for any grant of public money, was published in the same issue. At a meeting of the London Education Committee, when the reports were presented, the temporizing conclusion was come to that, in districts where there is no prospect, within a reasonable time, of utilizing existing institutions, the Council should itself make suitable provision "if thought desirable." Since then the Council has decided to secure treatment for the children by utilizing existing institutions and making grants in return from public funds. The governing bodies of some of the hospitals have, we believe, given their assent to this scheme, apparently without consulting the medical staff, on whom it is thus proposed to throw additional work. At other hospitals the matter is still under consideration. For this work the hospital will be paid, but, as far as the medical staff is concerned, it seems to be expected that virtue will be its own reward.

In connexion with this subject we would call the attention of the London County Council to a document, published in this issue (page 1462), in which the Court of Governors of the Royal Hants County Hospital has expressed its feeling that, "having regard to the heavy demands that are made upon their staff, they would not be justified in allowing general treatment of the numerous cases that must arise as the result of the medical inspection provided by the Act referred to, and they desire to suggest that the Local Education Authority should, before these questions arise, proceed to make arrangements for the discharge of these duties by the medical men in their respective districts, which they have ample powers to do."

Against the proposal made by the London Education Committee, a strong protest has been made by the Metropolitan Counties Branch in a letter sent to all the members of the staffs of London hospitals. In that letter the case is put with lucidity and force. Reference is made to the enormous number of children found defective on medical inspection; it follows that provision must be made for the treatment of diseases of the eyes, ears, throat, teeth, and other obvious defects, and this, in the words of the letter, "involves a large increase of the unpaid work already done for the community by the medical profession."

It is the duty of the State to do its utmost to prevent the physical deterioration of its citizens, on whose efficiency the future of the nation depends. But the State has no right to do this at the expense of medical charities supported by voluntary contributions—still less by making further exorbitant demands on their medical staffs. The Education Committee, in fact, proposes to create a new form of hospital abuse which will not only intensify the feeling of the general practitioner on the subject, but will inflict a cruel wrong on the children. Abundant evidence was obtained by the Day Schools Committee, the report of which was published as an

appendix to that of the Special Subcommittee already referred to, showing that it was impossible for the hospitals to deal adequately with the very common forms of childish defects (vision, hearing, ringworm, teeth), while they found it equally difficult to deal with chronic cases requiring prolonged treatment, such as tuberculosis. The map of the County of London, including the City, showing the educational administrative areas, the number of school children in these areas, and the position of general and special hospitals, provident and free dispensaries and Poor Law infirmaries, published in the JOURNAL of January 9th, shows at a glance that the institutions for medical relief are to a large extent grouped in the central districts. It is obvious that this fact alone makes it practically impossible for vast numbers of the children within the area of jurisdiction of the London County Council to be taken to the hospitals at all. In the case of many children, the loss of time caused to parents or others by taking them there will deprive them of the opportunity of being treated. In the case of those who are taken, the difficulty of transport, with the exposure to weather and other possible mischievous influences, the length of time they have to wait before being seen, and the perfunctory manner in which, owing to the already overcrowded state of the out-patient departments, it is likely they will have to be dealt with, made up a combination of factors calculated to render the treatment nugatory, if not worse.

We have reason to believe that a considerable number of the members of the staffs of London hospitals are in agreement with the views expressed in the letter of the Metropolitan Counties Branch. Some may be expected to dissent, because the smaller schools find it not an altogether easy matter to get a sufficient number of cases which can be used for teaching purposes. But the interest of the public which subscribes the money for their maintenance must prevail over that of any hospital school; and the welfare of the children must be placed before everything else. The only satisfactory solution of the question is, in our opinion, to be found in the establishment of school clinics in large towns, and in the recognition of the surgeries of private practitioners in rural districts. In either case adequate remuneration of those who do the work is an essential condition which should be insisted upon with the united strength of the whole medical profession.

INTESTINAL STASIS AND TOXINS.

Two distinguished British authorities, Sir Lauder Brunton and Mr. Arbuthnot Lane, have recently made public their views on the pathology and treatment of certain well-known chronic affections of the large intestine. Mr. Lane's address (p. 1408) deserves the attention of all who practise or teach medicine—the physician, the surgeon, and the obstetrician alike—for he discusses the cause of a condition familiar to them all. He observes that, while constipation is the most frequent objective evidence of unsatisfactory drainage associated with chronic intestinal stasis, it happens not uncommonly that there may be a daily evacuation or even diarrhoea. He insists, after relating the general changes which aid in the diagnosis of chronic intestinal stasis, that the symptoms are due in part to interference in the normal functioning, expressed

by pain, and in part to absorption of poisonous material, evidenced by toxæmia. The chief toxic symptoms, Mr. Lane reminds us, are headache, a feeling of mental and physical lassitude, an inability to perform the ordinary duties of life, mental misery and distress, nerve symptoms comprised usually under the term of "biliousness," and a want of control over the temper which renders these patients unhappy themselves and the cause of unhappiness to others.

Mr. Lane's conclusion that when the stage has been reached in which owing to delay in evacuating its contents the large bowel has not only ceased to perform a useful function, but has become a source of danger, its removal from the drainage scheme will be of great service to the body, will seem to many very bold, but if the long catalogue of evils which he attributes to intestinal stasis and the consequent absorption of toxins is proved, then it is obvious that the drastic remedy he advises must not be ruled out of court merely because of its boldness. Sir Lauder Brunton in a recent paper¹ insists on the importance of intestinal toxins produced and absorbed as a consequence of chronic colitis. He tells us that he has lately been struck by the frequency with which patients suffering from chronic colitis complain of being always tired—a symptom which he has found to be diagnostic in more than one doubtful case. We are here reminded of the feeling of mental and physical lassitude which Mr. Arbuthnot Lane signalizes as an essential indication of chronic disease of the large intestine. Mr. Lane ascribes the lassitude to toxic agencies; and Sir Lauder Brunton says that whereas he was once inclined to attribute the lassitude to the absorption of peptones or albumoses from the intestinal canal, the recent researches of Weichardt have led him to the conclusion that the weariness is more probably due to toxins formed by microbes. During the breaking down of albuminous molecules toxins may be produced possessing a special property of causing fatigue. Weichardt has shown that fatigue toxins can be expressed from exhausted muscles and made to produce fatigue in other subjects into which they are injected. On the other hand, fatigue antitoxins may be produced in the same way as other "anti" bodies—by the injection of small quantities into a horse, the dose being gradually increased until a great power of resistance has been obtained. Weichardt asserts that fatigue toxins can be completely antagonized by the administration of fatigue antitoxins, which afford the tissues a far higher degree of resistance to fatigue than they normally possess. Sir Lauder Brunton suggests that Weichardt's researches may solve the mystery of beef-tea and beef juices, which contain little nutritive material but yet possess a very considerable stimulant action. The meat juice, according to Weichardt's teaching, supplies a fatigue antitoxin, and is not simply a mild, second-rate nutrient, for its active power in removing or preventing fatigue seems to be altogether out of proportion to its nutritive value. Sir Lauder Brunton admits that he can give no rules for the administration of medicaments which will bring about the development of fatigue antitoxins, but he thinks that the introduction of large quantities of the lactic acid bacillus into the intestine, as suggested by Metchnikoff, acts by destroying the bacilli which produce fatigue toxins. As a practical physician, the same

¹ On Chronic Colitis as a Cause of Fatigue. *St. Bart's Hospital Reports*, vol. xlv, p. 1. (Lancet, June 12, 1909.)

authority dwells on the advantages of eliminative, as opposed to tonic, treatment in cases of chronic colitis. Iron and strychnine often fail, he reminds us, adding that Byron found a dose of Epsom salts more stimulating to the brain than a glass of champagne. Old-fashioned purgatives remove the sense of weariness present in many cases of intestinal catarrh, a fact quite familiar to the experienced practitioner. A small dose of castor oil, repeated every morning, is, Sir Lauder Brunton thinks, the best remedy for chronic colitis, although a subsequent course of intestinal irrigation at Plombières, or elsewhere, may be necessary. As Sir Lauder Brunton refers to Byron, we wonder what that noble but wayward bard, who sang of those sodas and magnesias which form "that bitter draught the human species,"² would have thought and written of the possible developments of fatigue antitoxins, a tragic theme to all who with unashful forehead woo the means of weakness and debility, as Adam says in *As You Like It*. Perhaps we may be prophets, and foresee a race who, with foreshortened colons, will forswear alcohol and carouse with elegant brews of fatigue antitoxins, abusing the latter as much as our own forefathers spoilt themselves with the former.

THE FINANCE BILL.

THE Finance Bill has now been published, and it has been possible in an article published at page 1429 to gauge more exactly than before how the Budget this year will affect medical men and the profession of medicine should the proposals made be accepted by the Houses of Parliament without material modification.

The taxation on motor cars as apart from motor cabs, omnibuses, and vehicles for carrying goods, has already been discussed in these columns. As medical men are to be allowed a rebate of one-half, the taxes in their case will be: For cars not exceeding 6½ h.p., 21s.; not exceeding 12 h.p., 31s. 6d.; not exceeding 16 h.p., 42s.; not exceeding 26 h.p., 63s. There are higher rates for higher powered cars, but these need not be considered, since few, if any, medical men buy for purely professional purposes cars which, when measured according to the Royal Automobile Club formula, exceed 26 h.p. So far, therefore, medical men may congratulate themselves. It is otherwise with regard to the petrol tax. This in their case, as in that of all users of petrol-driven cars other than cabs, omnibuses, and trade vehicles, will be 3d. a gallon. Mr. Lloyd George has consented to receive a deputation on the subject, and it is possible that medical car users may still be put upon the same terms as cab, omnibus, and trade vehicle owners.

The income tax proposals work out exactly as indicated in the article published in this JOURNAL on May 8th; the injustice of regarding an income derived from inherited property and one resulting from the provision for old age made by the individual himself as of precisely the same character, remains unremedied. Exemption from income tax, and even the ordinary rebatements made in the case of income tax under £700, are no longer to remain in the case of persons resident abroad. This will make a material difference in the case of a medical man who, having spent his working life in a tropical climate, wishes after retiring to reside in Southern Europe or elsewhere in a climate which suits him; by living abroad he forfeits his right to exemption or rebate, and in the case of a man who retires on a pension or other income of about £400,

this new regulation will mean a choice between endeavouring to live on about £375, less any local income tax, and taking his chance in England.

The effect of the new proposal with regard to estate and legacy duties is not easy to determine; but in the case of estates which for probate purposes are regarded as exceeding £15,000 in value the additional payments will clearly be very heavy. With regard to smaller estates, such as those commonly left by medical men, one might suppose at first sight that the effect of the new regulations will work out favourably; but on examination it is found that the bill takes away with one hand what it apparently gives with the other. The only way to determine the net result is to take a number of hypothetical estates of small value and calculate what they would pay under the present regulations and under those now put forward. It then becomes clear that the sums which in future medical men will have to accumulate for the benefit of their children will have to be materially greater than the sums which they at present aim to leave behind them if they wish their children to obtain the same benefit as they would have received heretofore. A medical man, for instance, who dies leaving an estate of £7,500 which he desires to tie up in some fashion for the benefit of his daughters may safely count upon the Government relieving them of the care of practically the whole of the odd £500, if not a good deal more.

All transfers of property will entail a very much heavier expenditure in stamps than hitherto, but the new taxation on supposed incremental values of land—unlikely to affect the majority of medical men—will not be operative in the case of hospitals and some other institutions. The same is true of the clauses which render liable to taxation gifts of real or personal estate made within five years of the death of the donor.

The taxes hitherto mentioned may be regarded as affecting individual medical men rather than the profession of medicine as a whole. It is the reverse with the increased imposts on alcohol and the taxes mentioned in the second section of the third schedule to the Act. Taking these together, it may be said that they will work out very hardly in the case of a great number of individual medical men, that they will do something towards increasing the financial difficulties of many hospitals, and that they will handicap every medical man in the performance of his work. As regards the first point, the increased taxation of potable spirits of every kind, and whatever their purpose, will make it more difficult for medical men engaged in contract practice and obliged by their agreements to supply medicines as well as advice to fulfil their obligations without direct loss. As regards hospitals, their dispensary bills, which are already very heavy, will be gravely increased both by the additional price of alcohol and the imposts on chloroform, ether, collodion, ethyl chloride, and other like drugs.

As for medical men as a whole, they perhaps need not worry, because their better class patients will be charged higher prices for medicines containing or prepared with alcohol by pharmacists, but they will be puzzled how to deal with those whose means they know to be strictly limited. It is always difficult to combine scientific soundness and practical feasibility in the advice given to such patients, and medical men will be still further handicapped in their task when medicines have to be chosen into the preparation of which little or no alcohol enters. When in-

² Don Juan, Canto X, 17.

creased taxation becomes necessary, it is always on the poorer members of the community that the new burdens press most heavily in the long run. This is probably inevitable, but it might have been expected that the public would be spared in the special direction under consideration. In particular, the taxes on chloroform, ether, and other alleviators of pain and distress seem to us simply wicked. A benevolent and far-seeing Government will kindly abstain from charging the purchaser of a gallon of whisky more than 15s. odd for a carouse for himself and his friends, but if in the hope of saving his fellows from horrible agonies a man buys the same quantity of ether it will mulct him to the extent of £1 16s. 6d., adding about 7s. to that sum if his choice falls on chloroform. It has thus been reserved for Mr. Lloyd George to suggest a variation of one of Shakespeare's most familiar sayings: "The quality of mercy is not strained but it shall be heavily taxed."

It is expected that the opposition to the Finance Bill will centre round the land clauses, which introduce taxes of a novel kind, and to which many persons are bitterly opposed. As these clauses have been placed in the forefront of the bill, the fight may be expected to begin in earnest as soon as the Committee stage is reached, and it is probable that provisions more nearly affecting the medical profession will not be reached for several weeks or even months.

HYGIENE AND TEMPERANCE IN THE PRIMARY SCHOOLS.

THE British Medical Association comes in from time to time for a good deal of criticism, and for our part we do not think that this is a matter for regret. Any man or organization which does things is certain to be criticized; they will be criticized by people who are fond of quoting Lord Melbourne's interrogatory response. Why not leave it alone? they will be criticized by people who really believe that mistakes are being made; and they will be criticized by those intangible folk who say that they quite approve of the purpose, but object to the means taken to bring it about. But things cannot be left alone when they are evil in themselves, and the seeds of worse evils in the future. Over thirty years ago Parliament, in response to the demands of an unmistakable public opinion, enacted that education should be compulsory for all, and naturally enough the first idea of educationalists, having caught our young barbarians of the poorer classes, was to give them an education in books, modelled so far as it could go on the book education given to the wealthier young barbarians. The statistics of recruiting, rubbed into the public mind by the unfortunate incidents of the Boer war, aroused the country to a consciousness of the fact that all was not well with our system of elementary education, that it was grossly defective in that no attempt was made to inculcate the first principles of personal and domestic hygiene, nor to promote physical development by suitable training, and the removal of causes of physical deterioration. This, then, was one of those things which could not be left alone, and we believe that for once in a way the British Medical Association escaped criticism when it stood forward as the exponent of medical opinion on the subject. It did this in many ways, but we are now only concerned with the representations it made to the Board of Education five years ago as to the urgent importance of giving elementary scientific instruction in health subjects, including temperance, in all primary schools.

A resolution to this effect, adopted by the Central Council and subsequently approved by the Representative Meeting, was submitted to the President of the Board of Education on behalf of the British Medical Association, by the then President, Dr. Griffiths of Swansea, who was one of the Representatives of the Association who took part in the deputation which went to the Board in July, 1904. The official response on that occasion was indecisive, stress being laid upon the difficulty of providing teachers adequately equipped to give instruction in hygiene and temperance. The efforts of the British Medical Association and of its JOURNAL to instruct public opinion were, however, not remitted, and the institution of compulsory medical inspection by the direct act of the House of Commons put the matter on another plane. In the Annual Report of the Board of Education issued last March, it was stated that a new syllabus in hygiene had been framed for students in training colleges, and that the Board's final examination for its students would in future include a paper in hygiene containing questions based on this syllabus. We are now able to announce that the Board has taken a further step forward. It has issued a syllabus of lessons in temperance for scholars attending public elementary schools, which we are enabled to publish in the SUPPLEMENT for this week. The Board directs that in future this syllabus shall be used by all teachers in public elementary schools, and suggests that at least three lessons in the subject should be given to the children in each school year. This, of course, is not very much, but it is a beginning, and the prefatory note rightly points out that the teachers on the staff of the school will find frequent opportunities, apart from the regular lessons, of impressing upon the scholars the importance of habits of self-control. The syllabus, it will be seen, is drawn on thoroughly practical lines; the first section deals with the subject of food and its use, including the use of beverages, with a brief reference to the fact that alcoholic beverages contain little or no real food substance; the second gives some account of the effects of alcoholic beverages on the body; and the third, intended only to be used in the instruction of children over twelve years of age, sets out more in detail the evil consequences of intemperance to the individual, to the home, and to the State. The prefatory note rightly impresses upon the teachers the impropriety of exaggerated statements, and directs that the instruction should be of a kind to make a sober appeal to such reasoning capacity as a child possesses, and to the ideas of decent, self-respecting, and dutiful living which every good teacher endeavours to present to and to cultivate in the children under her charge. The Representative Meeting at Caxton Hall in 1906 urged as one of the reforms most urgently necessary the establishment of a medical department within the Board of Education, and pressed the matter upon Mr. McKenna, the then President of the Board. This recommendation was carried out by Mr. McKenna in 1907 by the appointment of Dr. George Newman to be chief medical officer to the Board of Education. We may look upon the syllabus to which we have referred as one of the firstfruits of the expert advice which the Board has received in this way and as a proof of the great value of the creation of a medical department.

THE ANNUAL MEETING.

In the SUPPLEMENT for May 22nd was published the provisional agenda paper for the Annual Representative Meeting this year, and in the SUPPLEMENT for this week will be found the programme of the Annual

General Meeting of the Association and its fifteen Sections, which begin their sessions on Wednesday, July 28th. In some instances it has been possible to publish brief synopses indicating the scope of the remarks by which the subjects selected for discussion will be introduced. That it is not possible to do this in all cases is a matter of regret, and we would appeal to those gentlemen who have not yet complied with the requests addressed to them to do so at the earliest opportunity, for there can be no doubt that a discussion is usually more fruitful and interesting if those who take part in it have had the opportunity beforehand of considering the line of argument to be followed. Elsewhere in the JOURNAL will be found the third of a series of articles of a general character dealing with the arrangements for the meeting. The first article, published last December, contained a description of Belfast, its public buildings and trade; the second, published in January, described its college and hospitals; the third, which appears this week, gives some account of the surroundings of Belfast and the opportunities for recreation which the north of Ireland affords. All these articles have been copiously illustrated by the reproduction of photographs supplied to us by Dr. Cecil Shaw, of Belfast, and for the most part specimens of his own skill as a photographer. In a later article it is intended to give a general account of the arrangements and entertainments, the train service, short excursions round the city, and some particulars regarding the journey from London, the north and south-west of England, Wales, and Scotland. In a recent issue we stated that there was reason to believe that an invitation would be received to hold the annual meeting of 1911 in Birmingham, and of 1912 in Liverpool, but that nothing had been definitely settled with regard to 1910. We understand that a plan with regard to that year is under consideration, and that it is possible that an announcement on the subject may be made at an early date.

SPIRITUAL HEALING.

In the *Transvaal Medical Journal* for March we find a typical example of the utter disregard for truth often shown by patients who testify to cures supposed to be wrought in them by spiritual healers. Dr. Arthur G. Brinton, of Johannesburg, quotes the following extract—published about November, 1908—from *God's Latter Rain*, which appears to be the official organ of a local religious sect: "Letis Saunders, of 32, 'De Korte Street, Braamfontein, Johannesburg, testifies: 'My eyes were so bad, my sight was almost 'gone, and my eyes were sunken and withered. I 'was treated by several doctors—Dr. Brinton, an 'eye specialist. Dr. —, and Dr. — (we do 'not think it necessary to give the names), and 'others. The doctors said my sight had always 'been defective and could not be healed. I went 'to the tabernacle and Jesus healed me as the 'brothers prayed. Now my eyes are perfectly well 'and all the pains are gone.' We do not mean for a moment to call in question either the efficacy of the brethren's prayers or the good faith of the patient. But the brethren themselves would doubtless wish that the truth should be made manifest, and it is fortunate that they have had their wish. Dr. Brinton gives an extract from his case book from which it appears that the patient was sent to him five and a half years before the date of the statement above quoted. She was then 9 years old. A comparison of his notes taken at the time with the girl's testimony shows that the statement attributed

to him is inaccurate in every particular. Her vision was perfect; her right eye was normal, while there was nothing wrong with the left eye but some slight scarring, probably left by phlyctenular conjunctivitis from which she had suffered before she came under his care. This scarring, as Dr. Brinton says, would in all probability have yielded naturally in the course of the five years to the use of the yellow oxide of mercury ordered by him. We repeat we do not mean to insinuate that the poor child was consciously lying when she testified to the remarkable cure of non-existent disease. Her statement, like that of all the testimonies as to Christian Science and other forms of spiritual healing that can be brought to the test, is obviously the result of auto-suggestion stimulated in an ignorant mind by an atmosphere of unwholesome religious excitement.

MEDICINE AS A SOURCE OF INCOME.

At page 1431 of this issue will be found an article dealing with a subject of great interest to all medical men, and to all those who are ever called upon to give advice as to the choice of a career. The profession of medicine does not, of course, depend for its attractions solely on the amount which those who adopt it as a career may expect to obtain in the way of income. Nevertheless, in the vast majority, if not in all cases, this must be regarded as a very important consideration. How far it is common for medical men to enter on the actual practice of medicine without any capital whatever may be a moot question; but since a medical education is very expensive and the acquirement of a practice either by purchase, or by setting up house and waiting until patients come, may well absorb quite an average fortune, it is to be feared that no large proportion of medical men has means other than those drawn from their labours year by year. In such case the difference of a few pounds in the year's income one way or the other may make all the difference between comfort and discomfort, and it is indubitable that of late years complaints as to undue difficulty in making an adequate income have been increasingly frequent. It is possible that such complaints are sometimes exaggerated, but unfortunately one meets commonly with distressing evidence that many of them are only too true. In any case it is assumed in the article that it really is more difficult to gain a satisfactory livelihood from practice than it used to be, and an attempt is made to discover whether, when things as they now exist are contrasted with what they were twenty-eight years ago, any difference is discernible which would naturally tend to make the practice of medicine a less paying calling than formerly. It is admitted that a complete answer to the question involved must depend upon consideration of a great number of different factors, and in this article, which is based on painstaking and laborious investigation, no attempt is made to deal with more than one of them. Its net outcome is to show that one striking difference in the conditions of practice between the beginning and the end of the period investigated certainly exists, and that it is of such a character as to be likely to add to the difficulties which a man of average ability and average opportunities may expect to encounter in gaining a living by practice. The whole case, however, cannot be considered to be proved until other investigations along the same line have been completed and analogous conclusions are shown to result from them. The results of one of them will be published at an early date.

THE REVOLT OF THE HERBALISTS.

THE inquest in a case which had been attended by a herbalist, to which reference was made in the medico-legal notes in last week's JOURNAL, has been followed by a local demonstration by the so-called People's League of Medical Freedom. Under the auspices of this league a public meeting was held at Sowerby, a village on the fringe of the Yorkshire moors, to protest against the action of the Halifax District Coroner (Mr. E. H. Hill) in connexion with the *post-mortem* examination and inquest. Quaint customs die hard in remote places. There are districts where the village herbalist still has a following, and any attempt to restrict his or her pretentious practices are strongly resented by the villagers. Lovers of freedom and liberty in medicine were invited to the meeting "to resist the tyranny of medical priestcraft." The proceedings were enlivened by the presence and speeches of Mr. W. H. Webb, a Southport herbalist, and proprietor of the *Herb Doctor*, and Mr. J. P. Swan, Honorary Secretary of the People's League, of which the *Herb Doctor* is the official organ. With a touch of unintentional but ironical significance, a press report says: "Darkness closed in on the meeting, the resolution was put without delay, and was carried without dissent amid loud applause." The resolution expressed indignation at the action of the coroner. Two grievances were resented. It was alleged that the inquest should not have been held, and that the herbalist should have been called to give medical evidence. Regarding the first point, the discretion is properly in the hands of the coroner, to whom the facts and circumstances are communicated. The second point raises an altogether insupportable claim. It is preposterous to suggest that a coroner should accept medical evidence as to the cause of death from persons who have had no medical training. Mr. Swan is reported to have said: "Medicine is an Art, and therefore a great doctor was 'born, not made. The success was to the man with 'superior instinct.'" This is an age of prodigies, but we are not aware of the existence of any individual born with a knowledge of anatomy, physiology, or pathology. Artfulness (not Art) and superior instinct may be useful in impressing other people that one possesses knowledge and ability where neither exists, but these are precisely the elements which make the empiric and the quack. It would be interesting to know the constitution and membership of this league with the high-sounding title. The agitation for medical freedom of the kind desired by this league is promoted by means of much misrepresentation as to the meaning and intention of the Medical Acts now on the Statute Book. These are framed in the public interests, and not for the benefit of registered medical practitioners, as often alleged. Other comments on the eccentricities of the People's League of Medical Freedom appeared in the JOURNAL on May 23rd, last year.

TYPHOID CARRIERS.

A MEMORANDUM, addressed to hospital physicians and others who may be called upon to deal with typhoid fever cases, has been issued by Dr. D. S. Davies, M.O.H. Bristol, suggesting that, in view of knowledge recently acquired as to the risk of continuously-infected persons known as "carriers" maintaining and distributing typhoid fever infection, physicians—especially those attached to public institutions—might do well to arrange to keep a register of convalescents and their addresses, with a view of securing their periodic attendance for a period of six months, in order to determine

bacteriologically their actual condition as to infectivity. The ultimate aim of any method adopted to check this source of infection must be the discovery of a method of cure, but it is suggested that in the meantime the circulation of simple rules among convalescent patients might lead to some diminution of typhoid, and with this object Dr. Davies appends a paper of instructions to typhoid convalescents. Dr. Davies makes reference to the report by Lieutenant-Colonel Semple and Captain E. D. W. Greig published in the *Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India*, the conclusions of which were stated in the BRITISH MEDICAL JOURNAL last September (vol. ii, 1908, p. 834). The inquiry confirmed the conclusion drawn from the cases reported at various times during the last few years in our columns, which is that persons convalescent from typhoid fever, and even in some cases persons who have had the disease years before, may harbour the bacillus, and become centres of small epidemics. This is more particularly true of individuals engaged in the preparation of food. There can be no doubt that the solution of the problem of how to treat these persons so as effectively to free them from the bacillus would be a most important step in advance, and would eliminate one most insidious cause of the continuance of the disease, and of the occurrence of so-called sporadic cases. The fact that the medical officer of health of an important English city has felt it advisable to invite the profession in that city to co-operate with him to this end, may perhaps be some consolation to Captain Clive and Mr. Ward, who, as will be seen by a paragraph in our Parliamentary Notes this week, are much exercised because certain soldiers who harbour the bacillus are being detained under treatment in the Millbank Military Hospital.

MILK AND DAIRIES BILL FOR SCOTLAND.

THE Milk and Dairies Bill introduced by Mr. Burns on May 25th, and analysed in the SUPPLEMENT for last week, is to apply, with certain necessary verbal alterations, to Ireland, but is not to extend to Scotland. The reason for this is that on the previous day the Secretary for Scotland introduced a Milk and Dairies Bill for Scotland into the House of Lords. The text of this bill was not available until after Parliament had adjourned for the Whitsuntide recess, and we were therefore unable to publish an analysis of its provisions last week; but such analysis will be found in the SUPPLEMENT for this week. The Scottish bill is generally on the same lines as the bill for England and Ireland, but appears to us to be in certain respects better. The appointment of a veterinary officer in England will depend upon a special order being made by the Local Government Board, whereas in Scotland, if we read Section 3 correctly, it will be incumbent upon the authority in every district to appoint such an officer. In Scotland the medical officer of health will be required to inspect every dairy annually, whereas the provision of the English bill on this head is permissive. The Scottish bill provides that a vehicle from which milk is sold shall be deemed to be premises, but we fail to find any such provision, which may prove extremely useful, in the English bill; nor do we see in the English bill a provision requiring the dairyman to produce a list of his customers and invoices in any case in which the outbreak or spread of infectious disease appears to be attributable to the milk. There are other points on which the two bills differ, but these appear to be the more important.

UNQUALIFIED PRACTICE.

THE inefficient nature of the Medical Acts for the prevention of unqualified medical and surgical practice is illustrated daily in the advertisement columns of the newspaper press, both in London and in the country. By means of specious advertisements, the ignorant public is deluded into entrusting the health of themselves and their children to those who, neither by course of study or professional knowledge, are fit and proper persons to undertake the important duties involved. Our attention has lately been called to a column advertisement in the *Leicester Daily Mercury*, headed "Blindness," which emanates from a limited liability company, styled Ison's Eye and Ear Dispensary, Great George Street, Leeds. Starting with extracts from the *Daily Mail*, in which the cause of blindness in many cases is imputed to neglect in infancy, and continuing with an extract from the *Lancet*, in which some years since the importance of special study for medical practitioners in eye diseases was made the subject of comment, it proceeds to eulogize the "life study" of one Thomas Ison. "Oculist and Aurist," and to inform the public that he is in a direct line of descent of those who have made a study of such diseases for upwards of sixty years. It is added that "none should attempt to cure its defects but those 'who have made a thorough study of the diseases 'to which it—the ear—is peculiarly liable.'" This information is somewhat discounted by the fact that Mr. Ison is not a qualified practitioner in any respect, and it is as well that the public should realize that the titles, "Oculist and Aurist" are self-assumed, and, therefore, of no value as a mark of any special knowledge of the subject about which he writes and advertises himself. It will be remembered in this respect that Mr. Ison was prosecuted by the Medical Defence Union in 1906 before the stipendiary, and convicted under Section 40 of the Medical Act, 1858, for assuming titles implying that he was recognized as a surgeon, and subsequently converted himself into a limited liability company, and thus presumably ended any further liability under the Act. It will also be remembered that a bill to prevent the practice of medicine and surgery by limited liability companies was passed by the House of Lords and sent down to the lower house about two years ago, but since that date no further progress has been made in this direction. The advertisement of Ison's Eye and Ear Dispensary, Limited, is an object lesson, and affords a concrete instance of the need for amended legislation. To comment by advertisement upon the dangers of neglect in infancy in order to tempt unwary parents to continue such neglect by placing their ailing children under the treatment of an unqualified practitioner would be amusing if it were not dangerous. It must be remembered that under the "Children Act" failure to provide adequate food, clothing, and medical aid is now deemed to be neglect in a manner likely to cause injury to health. It cannot be too forcibly brought home to parents that to entrust the care of their children to quacks is a statutory offence which makes them liable on conviction to a penalty.

CONGRESS OF OPHTHALMIC SURGEONS.

THE meeting of ophthalmic surgeons that for some years past has taken place at the conclusion of the post-graduate course in ophthalmology at Oxford will be held this year on July 15th and 16th. The following programme has already been arranged. Demonstration of a case of leprosy under treatment, by Mr. Treacher Collins. (1) Address on *sérothérapie*

paraspécifique, (2) demonstration of intravenous injections, by Dr. Darier (Paris). (1) Operation for detached retina, (2) address on treatment by yeast serum in eye diseases, by Professor Deutschmann (Hamburg). Address on difficult iridectomies, by Professor Dufour (Lausanne). Demonstration of several new phenomena connected with colour vision, by Dr. Edridge-Green. (1) Address on the etiology of trachoma, (2) demonstration of the microbes of trachoma, by Professor Greeff (Berlin). (1) Address on muscle defects, latent and actual, (2) a new test for vision—the diaphragm test, by Mr. Bishop Harman. A series of microscopic specimens of the iris after iridectomy, showing the absence of cicatrization, by Dr. T. Henderson. Demonstration of his operation for glaucoma on pig's eyes, by Colonel H. Herbert. Address on some lacrymal gland cases, by Dr. Hill Griffith. Demonstration of the methods and appliances employed in the estimation of the working capacity of injured workmen, Mr. Jameson Evans. (1) Operation for ptosis and for glaucoma, (2) demonstration of test for binocular vision, by Dr. Freeland Fergus. Head specimen for demonstrating operations, by Dr. Knapp. Demonstration of the Mendelian theory and its application to ophthalmology, by Mr. Ormond. The use of radium in eye disease, by Mr. Arnold Lawson and Dr. Mackenzie Davidson. Some x-ray pictures will be shown by Dr. Mackenzie Davidson. Microscopical demonstration of the bacteriology of corneal ulceration, by Mr. A. McNab. Operation for ptosis, by Dr. Motais (Angiers). Demonstration of his diploscope, by Dr. Rémy (Dijon). Address on the significance of optic neuritis, by Dr. Risien Russell. Operations for (1) muscle advancement, (2) marginoplasty for entropion, by Dr. Story. Stereoscopic demonstration of the structure of the eye, by Professor Thomson. A scotomograph with stereoscopic fixation will be shown by Mr. Tomlinson. In addition there will be several interesting cases shown at the Eye Hospital. Surgeons who desire to attend can be accommodated to the number of seventy at Keble College at the rate of 7s. 6d. per day. A dinner will be held in Keble Hall on Wednesday, July 14th. At the conclusion of the meeting a launch will leave Folly Bridge on Saturday, July 17th, to go down the river to Reading. Further particulars can be obtained on application to Mr. R. W. Doyne, 30, Cavendish Square, London, W.

THE LATE MR. SIMEON SNELL.

DR. RICHARD A. REEVE, of Toronto, President of the British Medical Association in 1906, writes: By a regrettable mischance the issue of the *JOURNAL* of April 24th was mislaid and overlooked, so that I was unaware of the passing away of our lamented President for several weeks after the sad event. I was quite shocked to hear of Dr. Snell's death, and I would like to add my tribute of appreciation of his good work and solid worth. I had known him for a number of years and had formed a high estimate of his character, wide experience, and professional acquirements—an opinion which, I believe, was shared by not a few of his *confères* on this side of the Atlantic. His geniality and wholeheartedness were much in evidence; as an instance, I recall with pleasure not only his successful conduct of the Section, but his generous hospitality to the members, at the Portsmouth meeting. One could not fail to recognize the energy, ability, and thoroughness which Dr. Snell displayed in all his work—qualities, indeed, which marked him as a worthy member of the British School of Ophthalmologists. One cannot but feel that the demise of such a man will be a distinct loss even to so great a body as the British Medical Association.

Medical Notes in Parliament.

[FROM OUR LOBBY CORRESPONDENT.]

Typhoid Carriers.—Some little time back Captain Clive asked a question about the detention in hospital of soldiers who had contracted enteric fever in India, and on their return to this country had been found to be enteric germ-carriers. Mr. Haldane said that the question evidently referred to the seven non-commissioned officers and men under treatment at Millbank Military Hospital. He was informed that the condition of these cases rendered them dangerous to their comrades in barracks. It was, therefore, decided, on the recommendation of the Army Medical Advisory Board, to place them under special treatment to see if their condition was curable. This treatment had met with encouraging results, and one at least of the cases, it was hoped, had been cured. Although patients in hospital, they were allowed considerable freedom, and were not treated as ordinary patients, but rather as convalescents. They would be free so soon as the danger of the bacilli which they had brought to this country had been removed. Mr. Clive asked if the theory of germ-carrying was not quite unproved. Mr. Haldane replied that he did not think so. The advance of medical science on this subject within the last two years had been enormous. Mr. Ward asked if the experiments were being made with the sanction of the men and whether they would be poisoned in case of permanent injury. Mr. Haldane said he did not know why the treatment was referred to as an experiment; it was a well-known ascertained cure. Last week Mr. Ward resorted to the matter and asked whether these men had given their sanction to the experiments being made, and whether, if the treatment impaired their health they would be granted pensions. Mr. Haldane, in a written answer, replied that the proposed treatment was fully explained to the patients who, far from offering any objection, were greatly interested in what was being done. Apart from their liability to infect others, they were in exceedingly good health and the possibility of permanent injury to their health from the treatment need not be contemplated. Papers on the subject would very shortly be laid on the table.

Indian Medical Service.—Mr. Mooney asked the Under Secretary of State for India whether it was the policy of the Government of India to make use of the civil branch of the Indian Medical Service as a reserve of officers for the Indian Army; whether it was proposed in case of war to withdraw officers of the Indian Medical Service from the posts which they hold at present in all the important civil medical institutions; and, if so, whether any provision was or would be made to fill their places? Mr. Hobhouse answered that the civil side of the Indian Medical Service was intended to be used to a considerable extent as a war reserve; but the officers holding the more important and specialized posts in civil medical institutions were not regarded as a part of the war reserve.

Dispensary Doctors (Ireland).—Mr. Ginnell asked the Chief Secretary for Ireland how long the Local Government Board for Ireland allowed a dispensary medical officer to continue incapable from excessive indulgence in intoxicating drink before taking action; and what precautions, if any, the Board took for the lives of the poor, who had no choice of medical practitioner, after the Board had learned that the officer was addicted to this vice? Mr. Cherry replied that the hon. member was in error in assuming that action was not taken at once when a complaint was made officially to the Local Government Board that a medical officer of a dispensary district had become incapable of discharging his duties owing to excessive indulgence in intoxicating drink. The medical officer, however, could only be deprived of his post on sufficient grounds, which should be established at a public inquiry where he could be afforded a full opportunity of offering a defence. Allegations of intemperance contained in anonymous letters or made by individuals who refused to permit their names to be

disclosed, would not be a proper basis for an official investigation against a medical officer. The boards of guardians were charged with the supervision of the medical officers, and were assisted in that duty by the Local Government Board's medical inspectors. In addition, the poor might at all times complain against medical officers either to the guardians or the Local Government Board, and in that way secure redress and efficient medical attendance.

The Colonies and Malaria.—Mr. Ramsay Macdonald asked the Under Secretary for the Colonies whether the eleven Colonies which made no special report on malaria, in response to the circular of June 6th, 1906, had since been communicated with, and had been asked to furnish reports. Colonel Seely said that a special circular had recently been sent out by the Secretary of State with a view to obtaining fuller information with regard to anti-malarial measures, both from the Colonies referred to and from other tropical colonies. Mr. Ramsay Macdonald then inquired as to St. Kitts-Nevis, where nothing had been done to destroy the breeding places of malaria-carrying mosquitoes. Colonel Seely replied that the Secretary of State had made no further representation to the Government of St. Kitts-Nevis in this matter. He feared that effective action in this direction might be hampered by financial considerations, but the officer administering the Government would be asked for a report on the possibility of taking action. Mr. Ramsay Macdonald then referred to the opinion expressed by the Administrative and Executive Council of the Colony that rules for the suppression of mosquito-borne diseases, including malaria and yellow fever, were *ultra vires*. Colonel Seely answered that the incident referred to took place in 1906, and there had been no recent correspondence on the subject. The Secretary of State would now call upon the Governor to furnish a report as to the measures taken in the Bahamas to combat tropical diseases. It had to be remembered that legislation and expenditure in this colony were dependent upon the consent of the House of Assembly, which was an elective body.

The Madras Medical College.—Mr. Mooney asked the Under Secretary of State for India whether the present President of the Medical College, Madras, was appointed to that post after having acted as Surgeon on the personal staff of three successive governors of Madras; and what educational experience this gentleman possessed to qualify him for his present appointment? Mr. Hobhouse replied that the present principal of the Medical College, Madras, was Surgeon to the Governor of Madras from May, 1892, to February, 1902. He had also held various other appointments in the medical service, and was Professor of Medical Jurisprudence and Professor of Surgery for two and a half years before he became principal. The appointment was one for which the authorities in India were responsible, and the Secretary of State saw no reason to question the propriety of their selection.

The Public Health Acts.—Mr. Gladstone stated before the Whitsuntide recess that on the application of the local authorities orders had been made declaring Section 85 of the Public Health Acts (Amendment) Act to be in force in thirty-three boroughs and thirty-two urban districts. The Act did not empower a county council to apply for an order.

The Medical Acts Amendment Bill was withdrawn on Monday night last. It is understood that the bill will be introduced again shortly in an amended form, so as to place the question of the administration of anaesthetics in a shape less likely to excite opposition.

A SPECIAL meeting of the Council of the Charity Organization Society will be held on Monday, June 28th, at 4.30 p.m., at Denison House, Vauxhall Bridge Road, S.W., when Miss Amy Hughes, of the Queen Victoria Jubilee Nurses' Institute, will read a paper on provident nursing. Sir Alfred Lyall, G.C.I.E., K.C.B., will take the chair, and the Right Rev. the Bishop of Islington will speak.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

MANCHESTER AND DISTRICT.

THE LANGHO INEBRIATES' HOMES.

SPECIAL interest attaches to the annual report of the Langho Inebriates' Homes, in view of the fact that some time ago the Manchester Justices expressed a very unfavourable opinion as to the value of such institutions. At the beginning of last year there were 128 persons under detention, and 51 fresh cases were received; 14 were released on licences, 2 of which were revoked; 28 were discharged on the expiry of their sentences, 1 was sent to an asylum, and 1 readmitted, leaving 137 at the end of the year. Suitable occupation was given to the inmates, such as wood chopping, dairy work, and haymaking, while 35 women were engaged in laundry work, and others at sewing or rug making. Some of the well-conducted women, towards the end of their detention, were allowed to go out as charwomen in the neighbourhood, and the experiment was thought successful, as only 2 gave way to drink, and, besides being a source of revenue to the institution, it served as a sort of preliminary trial of their self-control previous to their dismissal. The Director complains that these and similar homes have gradually become places of detention for feeble-minded criminal drunkards, which will account for the fact that many of the patients after dismissal relapse into their old habits. The list of previous convictions recorded against the women sent to the homes averaged 28, though there seems to be some doubt in many cases. Exaggerated statements have from time to time appeared in the press as to the cost of treatment; in one case it was stated that a woman had cost the ratepayers £230, but on investigation it appeared that the actual cost of her detention for three years was a much smaller sum. Another press report said that it cost a certain authority 30s. a week for each inmate, whereas the actual cost for each woman during the last year was 14s. 3½d. a week, towards which the local authority paid 7s. 7d., the remainder being provided by the State contribution and the receipts from work done by the women themselves. During the year the women had earned altogether £981 actual cash profit, exclusive of work done for the institution. Referring to the question of the value of such homes, the Director urges that critics have not made allowance for the fact that by far the greater proportion of the cases are feeble-minded, and also that one special purpose of the Act was control by detention, which seems often to be forgotten. The majority of the women leave the institution with good intentions, but on returning to their own homes they are faced by want of employment and exposed to the temptations of old companions, and the unfortunate facility with which they can obtain a living by immoral practices often leads them to drink as a sequence.

WALES.

A CASE OF LEPROSY AT CARDIFF.

At the Seamen's Hospital, Cardiff, on June 1st, the Medical Superintendent discovered one of the out-patients, a Chinaman lodging in one of the Bute Street boarding houses, to be suffering from leprosy in a very early stage. Dr. Whelan immediately communicated with the port sanitary and municipal authorities, and since that time the patient has been the subject of a series of microscopic examinations. The result of these examinations seems to have confirmed the view as to the nature of the disease formed by Dr. Whelan, and the leper was admitted to the Seamen's Hospital and immediately isolated. Every other possible precaution has been taken by disinfection and other preventive methods, and a close examination has also been made as to the condition of all the other lodgers at the house where the patient stayed. Dr. Whelan is of opinion that the disease was originally contracted in China prior to the departure of the patient from Hong Kong in March, 1907. Dr. Fairfield Thomas, assistant medical officer of health, has reported to the Cardiff Health Committee that he had done everything possible with regard to the leper, the patient having been

isolated, and disinfection had been carried out very thoroughly. The question for the committee was the extent of its responsibility. It was of course responsible for the man's maintenance in the Seamen's Hospital. Legally he was destitute, and undoubtedly the guardians were responsible, but he did not know that the committee would care about shifting the responsibility in such a case.

SANITATION OF GLAMORGANSHIRE.

At the quarterly meeting of the Sanitary Committee of the Glamorgan County Council, held at Cardiff on June 4th, the County Medical Officer reported with regard to infectious diseases, that there had been an increase in the number of cases notified of small-pox, membranous croup, and puerperal fever, and a decrease with regard to diphtheria, erysipelas, scarlet fever, and enteric fever. It has been decided to provide a hospital with some 50 beds at Aberdare. The Caerphilly Hospital was opened for the reception of patients on April 27th. Several sites for a hospital for Neath Rural District have been inspected, and the District Council has given the Hospital Committee full power to deal with the matter. The alterations and additions in connexion with the administrative block of the Rhondda Hospital have been completed.

EBBW VALE DISPUTE.

The following paragraph appears in the *Western Mail* (Cardiff) of June 7th:

The two subcommittees appointed to arrange the terms of arbitration in the doctors' fund dispute at Ebbw Vale have met and discussed the question of arbitrators. The workmen's doctors' fund committee has selected Mr. Phil. Snowden, M.P., as their arbitrator, and the Cwm section has chosen Mr. Tom Richards, M.P. The doctors' committee so far has not accepted Mr. Richards. They do not object on personal grounds, but on the contention that it would be more satisfactory to have a perfectly independent person, and one who is totally unacquainted with the dispute. They hold the same objection to Mr. Brace, M.P., and would prefer the Cwm section to submit the name of a person outside the county of Monmouth. It is understood that the Board of Trade will be requested to nominate the referee.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

EXTENSION OF THE GLASGOW WESTERN INFIRMARY.

The building of the extension to complete the west block has now been commenced, and will be rapidly pushed on, as the builders are under contract to have the roof on by November. This addition will provide accommodation for 94 beds.

VICTORIA INFIRMARY, GLASGOW.

The post of visiting physician, vacant by the retirement, owing to the age limit, of Dr. Duncan, has been filled by the appointment of Dr. Love, who was so long associated with the late Dr. Finlayson at the Western Infirmary.

MEETING OF THE PHYSIOLOGICAL SOCIETY.

The experiment of holding a meeting of the Physiological Society in Glasgow was fairly successful. Comparatively few of the English members came north, but there was a good attendance of local members, and the contributions and demonstrations gave some indication of the scope and quality of the research work carried on in Scotland. The size and equipment of the physiological buildings was much commented on.

MEDICAL INSPECTION OF SCHOOL CHILDREN.

The Secondary Education Committee of the County of Lanark has prepared a draft scheme which provides for the co-operation of all the school boards. It is proposed to divide the county into districts, each under the charge of a medical inspector, who would be responsible for the work in that district. From five to seven medical inspectors would be required, and in order to supervise and co-ordinate the work of these inspectors the draft scheme provides for the appointment of a supervising medical officer, who would also collate and be responsible for the compilation of the statistics. As Dr. Wilson, the county medical officer, is willing to undertake this supervising and

statistical work, a considerable saving could be effected, as it would not be necessary to provide separate offices. This draft scheme was submitted to a large and representative conference of the school boards of the county, and, after a full discussion, it was decided that the representatives should confer with their boards and at a subsequent meeting decide whether they were prepared to adopt the draft scheme.

LUNACY IN SCOTLAND.

The general Board of Commissioners in Lunacy for Scotland have just issued their annual report. In it they state that on January 1st, 1909, exclusive of insane persons maintained at home by their natural guardians, there were in Scotland 18,197 insane persons of whom the Commissioners had official cognizance, including the inmates of the training schools for imbecile children and of the criminal lunatic department of Perth Prison. Of these, 2,682 were maintained from private sources, 15,464 by parochial rates, and 51 at the expense of the State. There is an increase in the number of insane during the past year of 289. The maintenance of this large number of insane amounted to £398,682.

Referring to the cost of district asylums, which is a heavy item of expenditure falling to be paid by the ratepayers, the Commissioners remark that the constant demand for additional accommodation for the insane, the large scale on which it has been found necessary in many cases to provide it, and the magnitude of the expenditure involved, have recently become the subject of much discussion. The Commissioners further state that for some time past they have urged upon district lunacy boards that all asylum buildings should be of the utmost simplicity compatible with efficiency for their general purpose, and that no expenditure should be incurred on external ornaments or in any other similar directions which are contrary to a strict economy and in no way contribute to the amelioration of the condition of the insane. It is hoped these pertinent remarks of the Commissioners will have some effect in diminishing the cost of asylums.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

IRISH MEDICAL BENEVOLENT FUND SOCIETY.

The annual general meeting of this society was held in the Royal College of Physicians on June 7th, when Dr. Andrew Horne, P.R.C.P., occupied the chair.

Annual Report.

The report of the Committee stated:

The total amount of the grants recommended since the last distribution is £1,327. The total number of applications considered during the year was 30. Of these 81 were from the widows of medical men, 5 from; or on behalf of their orphans, and 4 from medical men themselves. The number of applicants this year has been very large, and the amount given in grants has strained the resources of the Society, yet to many of the recipients the aid given has fallen very far short of their claims, and of their urgent necessities. The amount received through the central treasurer was £225 3s. 6d., as compared with £195 the year before. The subscriptions received from branch treasurers amounted to £315 16s. 2d., as compared with £351 11s. 3d. the year before. The Belfast and Co. Antrim Branch contributed £151 5s., including £5 5s. received late for audit the previous year. Since the accounts were closed a further sum of £9 15s. 6d. had been received from that branch. Of the £315 16s. 2d. received from county branches, £138 18s. 2d. should have appeared in last year's account, but was not received until that account had been closed. The branch treasurers doubtless do what they can to send their collections in time for audit. At present it is impossible to present the accounts in such a form as to make it easy to compare one financial year with another.

Mr. John Lentaigne moved and Dr. MacDowel Cosgrave seconded the adoption of the report. The former stated that there were about 3,000 members of the profession in Ireland, but only 500 contributors to this fund. Roughly, the amount of the subscriptions came to £541, while the amount paid out in awards was £1,327. There was a most serious falling off in the contributions from the branches. He thought one reason was that some medical men did

not know of the existence of the society and of the work that it was doing. This year they would try another plan, and he hoped that it would result in a considerable improvement in their funds.

Dr. Hastings Tweedy, Sir Lambert Ormsby, Dr. J. Magee Finny, Dr. Garland, Dr. Knox Durham, and the Chairman also addressed the meeting, and pleaded for liberal support of the society.

NEW CHILDREN'S HOSPITAL IN UNION INFIRMARY, BELFAST.

On June 3rd a large company assembled to join in the opening of the New Children's Hospital of the Belfast Poor Law Guardians. Dr. Bryars, Chairman of the guardians, heartily welcomed Lady Hermione Blackwood, who was to perform the ceremony, and other guests, and gave a short history of the movement. Lady Hermione Blackwood said the Belfast guardians had forestalled the findings of the Poor Law Commission, had segregated phthisical patients, built an admirable sanatorium, and now provided a separate block of buildings for a children's hospital, which enabled the classification in separate wards of medical, surgical, and special diseases. The true economy was to place a sick child under conditions of sunshine, cleanliness, and fresh air. The new block was then opened, and named the "Dufferin Children's Hospital," after the late Lord Dufferin. Sir John Byers, at the request of the Chairman, moved a hearty vote of thanks to Lady Hermione Blackwood, and said that the guardians could have got no more suitable person, as she was not only a daughter of a most illustrious Ulster house, but also a fully trained nurse and an inspector of Jubilee nurses in Ireland, who thus as an expert could keenly appreciate the enormous advantages of such an institution. A choir of the children sang "The Irish Emigrant," a song composed by Helen, Lady Dufferin, Lady Blackwood's grandmother.

The new hospital has eight wards, and accommodates 200 children. It is situated apart from the other work-house buildings, with large balconies facing south-west, and commanding a view of the valley for miles. It is built of red brick, and is three stories high. The main entrance is by a front central door with fireproof stairway rising to the top story. The separation of the children is well carried out in all details. The medical attendant will be Dr. Fulton, and Mr. Craig will have charge of the Eye, Ear, and Throat Department. Dr. Mary E. M. Logan will act as resident surgeon.

PROFESSOR FRASER.

A committee has been formed in Dublin to present Professor Fraser with some token of respect and admiration on the completion of his twenty-five years as Professor of Anatomy in the school of the Royal College of Surgeons in Ireland. It is felt that Professor Fraser's distinguished position as an anatomist, his lucidity as a teacher, and the unselfishness which has characterized his intercourse with students, deserve recognition from his former pupils, and subscriptions, not to exceed one guinea, may be forwarded to the honorary treasurer, Sir Arthur Chance, 90, Merrion Square, Dublin. The chairman of the committee is Mr. John Lentaigne, President of the College of Surgeons; and the honorary secretary is Mr. William Taylor.

HEALTH OF BELFAST.

At the meeting of the City Council on June 1st the medical officer of health reported that the death-rate from all causes for the past month had been 20 per 1,000, and from zymotic diseases 0.8 per 1,000. The number of infectious cases notified had been abnormally low.

The Harbour Commissioners and the City Council have come to an agreement which settles the dispute between the two bodies that threatened at one time to involve serious litigation. The Council will pay to the Commissioners £6,000 in full settlement of all claims for dredging of sewage of the town from the various channels.

The Local Government Board has refused to sanction the application by the City Council for a loan of £112,500 for the purpose of providing purification sewerage works, on the ground that the precise amount of purification is not evident; the resolutions dealing with the question were referred back to the committee.

Correspondence.

SPEECH FRIGHT.

SIR,—I liked your leader on "speech fright" very much, for it is a subject deeply interesting to all of us who have had from time to time to face the necessity of the responsibility for public speaking. But it disappointed me, too, for I had hoped for a scientific explanation of the curious but undoubted fact that a man who has been talking fluently and even eloquently as long as he retains his seat, begins to halt and stammer and even to break down hopelessly whenever he assumes the erect posture.

Cannot the physiologists help us? The ingenious Lauder Brunton has lately discovered, or popularized the discovery of some one else, that fatigue is due to a toxin developed in some mysterious way within the human body, and perhaps a microbe or some of those microscopic intruders may have something to do with the nervousness which afflicts most of us at inconvenient times; and I suggest this as a plausible line of investigation, to be carried out under the pecuniary auspices of the British Medical Association or the Royal Society. Meanwhile we must grin and bear the thorn in our intellectual flesh which Providence for some inscrutable reason of His own has planted there; and it is consoling to note that this form of temporary mental incapacity, sometimes running up to an absolute evaporation of words and ideas, is shared by some of our greatest orators. Lord Coleridge told George Russell that he once asked Gladstone if he ever felt nervous. "In opening often, in reply never," was the reply. And Lloyd George, so notorious for his glib tongue and nimble wit, made this confession to a friend: "When I was making my maiden speech I tell you I was in a state of misery. It is no figure of speech, but literally true, that my tongue clove to the roof of my mouth, and at first I could hardly get a word out." And Lord Althorp, the famous Prime Minister, said to Macanlay that he had only just got over his apprehensions. "I was as much afraid," he said, "last year as when I first came into Parliament. But now I am forced to speak so often that I am quite hardened. Last Thursday I was up forty times." Dizzy's famous breakdown is a matter of history, and Toby, in his inimitable style, has described the painful scenes he witnessed when Bob Lowe and the late Lord Derby came within more than measurable distance of total collapse. Probably some of your readers may have been present at the dinner given to my old friend, Sir John Tenniel, when the hero of the occasion, after helplessly looking round the room and stammering out a few words, abruptly sat down. This was when Birrell used the very happy phrase that this was one of the occasions when silence was more eloquent than words. But the great cartoonist told me afterwards that he had prepared an excellent speech, but when he stood up, absolute vocal paralysis seized him, and, unluckily, he had no text to fall back upon. In my own experience, I remember two occasions when I rose up to speak at public dinners, when my mind suddenly became a blank, and I was only saved from absolute disaster by some notes which I prudently had before me. I presume that temperament has something to do with this, for I have seen an Irish member, within a couple of hours of his introduction to the House, get up and hold forth with perfect fluency and confidence, and women are much less self-conscious on public occasions than men, and, take them all over, they speak much better than we do.

You have referred to various drugs taken by speakers to stimulate their oratorical powers and overcome nervousness. Wilberforce usually took an opium pill. Lord Granville in his *Life*, regrets having stood between Lord Beaconsfield and the House of Lords, because he heard afterwards that the great ex-Premier had swallowed something and inhaled something which timed him to speak at a particular moment; and it is broadly hinted that a very distinguished politician is in the habit of using whiffs of oxygen to recruit his flagging energies.

Stammering is, I suppose, a form of nervousness, and as a rule it cannot be overcome by any effort of will. But how curious it is that a man who stutters painfully in ordinary speech should be able to sing or read or make a

considered speech without hesitation. David Plunkett, whose conversational efforts were marred by painful hesitancy, was one of the few real orators to whom it has been my privilege to listen in the House of Commons. It seems evident to my mind, also, that animals are occasionally nervous. We know that a gun-shy pointer is only really food for powder, and another who blinks his points had better follow it into the grave as quickly as possible. The inexplicable in-and-out running of racehorses can only be explained in this way, and the irritating peculiarity of parrots in always declining to talk to order must certainly be due to a disinclination on the part of the bird to display its accomplishments "before folk."

But I could ramble away for ever over this fascinating theme, and I must now make room for others who, I hope will keep the ball a-rolling, and contribute their experiences and recollections for our interest and instruction.—I am, etc.,

Reform Club, June 8th.

R. FARQUHARSON.

SIR,—Your request to readers of the JOURNAL to give their experience in treating "speech fright" or the analogous condition of "stage fright" is one that I hope will receive the attention it deserves. Nothing that we can do earns us more gratitude than the relief of this most distressing condition, especially as on the concert or dramatic stage it is often the real artist that suffers most. For various reasons I have had many opportunities of treating these unfortunate people, and have been able to satisfy myself as to the right lines on which they should be treated. Bromides are worse than useless, and also other drugs with one exception. In many cases a placebo is all that is necessary; but there is no doubt that in others a dose of from 6 to 10 minims of vinum opii, given a quarter of an hour before the first appearance on the stage, is a remedy of very great value, and I have never found it leave any disagreeable after-effect, though, as you remark, Sir, it should obviously only be used under medical advice.—I am, etc.,

Birmingham, June 7th.

E. D. KIRBY.

SIR,—When I was a student at St. Bartholomew's (1870 to 1875) I remember well our revered teacher, Luther Holden, always recommended students who were nervous to take a $\frac{1}{2}$ grain of opium (or, at most, $\frac{3}{4}$ grain) just before going into college examination. A small dose of opium, as most people know, sharpens the wits and yet quiets the tumultuous heart; and also diminishes the secretion of urine, which is apt to be so excessive in the nervous state. Large doses of opium are, of course, foolish and harmful. On many occasions I have prescribed for nervous speakers 1 grain of opium in four pills, and one of the pills has been all that was required, a cup of good coffee after the mental effort recuperating the tired talker or performer and preventing any headache. Alcohol, as you wisely say, is the worst possible drug to try on these occasions.—I am, etc.,

J. KINGSTON BARTON, M.R.C.P. Lond.

London, S.W., June 6th.

SIR,—I have had success in the treatment of this complaint by suggestion, both with and without hypnosis. I gave a list of my cases up to the end of June, 1907, in the paper I read at the Annual Meeting of the British Medical Association in August, 1907; they were as follows:

- 28 cases treated.
- 23 cases results satisfactory.
- 5 cases improved.

Within the last few weeks I have treated two further cases: one, that of a medical student who had failed several times through nervousness at his *viva voce* examination. After one treatment, which I gave him the week he went up for his examination, he passed easily, and felt not the least nervous.

The second case was that of a lady who had to make a speech at a philanthropic meeting. She wrote afterwards, and told me that she was not a bit nervous, and was able to express herself fluently.—I am, etc.,

London, W., June 8th.

J. F. WOORS.

SIR,—In response to the invitation conveyed in the article on this subject in the JOURNAL of June 5th, I should like to say that I have had a long experience of the treat-

ment of such cases amongst voice users of all classes. There is no doubt that in a large proportion of cases medicinal treatment suitably administered has enabled the sufferer to overcome his trouble.

During the years that I was private assistant to the late Sir Morell Mackenzie, he used to treat large numbers of these cases with varying proportions of laudanum administered in strong coffee in doses of from 10 to 30 minims. I believe one of his prescriptions for some years went the round of the dramatic profession under the name of "First Night" or "Stage Fright Tonic." It is needless to say that the haphazard use of any prescription, no matter how eminent the prescriber, is doomed to failure in far more cases than it may chance to help.

The age, sex, and temperament of each patient have to be taken into account in treating this trouble. In some cases, owing to hereditary or acquired nervous peculiarities, no treatment is of any use for such special occasions, and no drug treatment that is not combined with efforts to improve the nervous stability is likely to be permanently beneficial, and may, if continued too long, lead to the worse evils hinted at in your article.

On general principles I do not think depressants such as bromides are likely to prove helpful. On the contrary, I believe the irritability present so often is the irritability of weakness, and that quite the opposite line of treatment is indicated. The patient is already sufficiently depressed by the accumulation of toxins in his system from increasing nervous metabolism as the time of trial approaches, as well as very often from other causes. The line of treatment should be by suitable diet, exercise, and, when necessary, medication, to get him into the best possible condition, and that this is the right course is shown by the success of those who have felt themselves able at the critical moment to dispense with drugs. When, however, one has to prepare such a patient for a near emergency, if time allows, it is well to order a calomel or other purge two days before "the great occasion," followed usually by a saline next morning. At a period of from fifteen to sixty minutes before the public effort has to be made the patient takes from 10 to 20 drops of laudanum in a small cup of pure strong coffee. Where a more sustained stimulation was desirable I have frequently added a few drops of tincture of cannabis indica with good results. In many cases the preliminary purge and the coffee will have the desired effect without the narcotics. Where these are given the medical man must exercise his own judgement and experience of such cases in hitting the doses likely to obtain the maximum and longest stimulating effect without risk of producing listlessness or even drowsiness later on in the performance. The purity and strength of the coffee is essential, and it would be better that the patient should take his dose of properly prepared coffee with him if the arrangements as to time are likely to condemn him to the use of any of the decoctions commonly sold under that name. The drugs should be prescribed in any suitable medium, with or without syrup, in a teaspoonful dose to be added to the coffee.

In a very great number of cases this treatment or the patient's faith in it has the desired effect. One cannot resist some scepticism as to what was the real share of the drug in people who never felt any need for such aid after the first occasion. There are, however, too many cases on record of eminent speakers, singers, and actors who have repeatedly felt the difficulties described, but who have been enabled to overcome them on these lines. Hypnotic suggestion has, I believe, been employed with good results in obstinate cases on the Continent, but I have no experience of its use in this country.—I am, etc.,

London, W., June 8th. J. G. DONALDSON, JAMES DONALDSON.

SIR,—If an etymology in one of the obscurer dictionaries were correct, the *Pharmacopoeia* itself would hold out a specific for stage fright in tinctura camphorae composita—"paregoric elixir." There is the general sense of "soothing" in *παρηγορέω*, *παρηγορικός*, like that of eloquence upon the crowd; the medical use of the word, however, is not metaphorical, but is derived from what the orator would take to allay his own perturbations when he stood up (— *παρά + ἀγος* —) in public.

I cannot now find my authority. One has seen a mental invalid called back for a time to intelligence and brilliance by a single dose of opium, and has known phosphorus carry through an examination a distracted and sleepless student.—I am, etc.,

Bristol, June 8th.

D. A. ALEXANDER.

SCHOOL CHILDREN AND THE HOSPITALS.

SIR,—May I be allowed to offer some comments upon the circular issued by the Council of the Metropolitan Counties Branch to its members on the subject of the treatment of school children?

As the circular indicates, parents able to pay for the treatment will be referred to their medical practitioner, and it is in reference only to those children whose parents cannot afford to pay that the Education Committee of the London County Council has recently issued to the London hospitals a letter of inquiry as to how far each is willing to assist in carrying out the treatment of certain ailments of the eye, ear, and skin. The circular calls on members of the Branch to oppose what is characterized as a proposal to take advantage of the voluntary hospital charities, because "it really involves a large increase in the unpaid work already done by the medical profession."

Although estimates exist as to the number of children suffering from the ailments in question, there are none, that I am aware of, which show the number of school children already being treated for them by existing institutions, and in default of such figures it is not possible to estimate what the increase in the number applying to hospitals would be if they were systematically notified by the school doctors. No doubt the effect at first would be to increase the numbers considerably, but when the arrears of these children had been cleared off the increase, if fairly distributed among existing institutions would not, I believe, be very great in any one of them.

Children, too, would no doubt come under treatment at an earlier age than at present, but this would not increase the total number to be treated.

If the x-ray treatment of ringworm proves to be as successful as expected, the number of children under treatment for that disease will very rapidly decline, and the unfortunately decreasing numbers in children attending the schools will tend in the same direction as regards all diseases.

The letter of the County Council is not a proposal to send an unlimited number of these children to hospitals, but an inquiry as to how far they are willing to co-operate with the London County Council: and to this inquiry the circular of the Branch suggests the reply, "Not at all!"—that is, the hospitals are to decline to continue treating any school children for these ailments, because there is a prospect of the number being increased.

The circular urges that the London County Council proposal involves a diversion of the funds of charitable institutions from the purposes for which they were intended. But why the treatment of ringworm and eye and ear affections, till now regarded as appropriate for hospital treatment, should become a diversion of hospital funds immediately that their importance is recognized by the London County Council is not apparent.

The connexion between the "principle" adopted by the Association that the out-patient departments shall be consultative institutions, and the inference drawn from it by the Branch, does not appear to be very close, but even if the consultative principle be accepted it does not appear to be infringed by a proposal that children shall be treated who come with a notification from a school doctor. If the "principle" involves that a child otherwise eligible for out-patient treatment (as necessitous children are) becomes ineligible when its ailment is discovered and notified by a school doctor, then I think the principle is unsound. The Branch portion of the paragraph is merely a statement of opinion, that a child eligible for treatment forfeits its right to it if its qualification is detected by the State—that is, the London County Council.

The circular further protests against capitation grants on the ground that it is "undesirable, and the attempt to allot such on hospital work would be obviously impossible." The impossibility is open to question, and as hospitals

receive payments from householders, from employers of labour, from public companies, from the Hospital Sunday Fund, and even in some cases from the Poor Law, giving in return letters admitting to treatment, there is nothing in their constitution or custom to prevent their receiving capitation grants from the London County Council. And the dictum of the Medico-Political Committee that capitation grants are undesirable, cannot be taken as the last word on the subject. Finally, the circular denounces the proposals as contrary to the public interest because the hospitals are in many districts not conveniently situated. No doubt this is so, but why it should be opposed to the public interest for existing institutions to carry on the work where they are conveniently situated, because in other districts it is not possible, is not apparent.

So far as can be gathered from the circular, it is proposed that the hospitals shall decline all cases of the diseases which the London County Council specially name as important to be treated. But it is to be remembered that all children of the hospital class are London County Council children, and, if the principle of refusing school treatment for these affections is to be carried out, all London children must be refused treatment for these complaints; it would be absurd to accept for gratuitous treatment a school child brought by its mother on her own initiative with ringworm or eye affection, and to refuse at the same time another of her children brought with the same affection, but with the notification of a school doctor, and for whom the London County Council offers a contribution to the hospital funds. Both are school children, and, if one is to be refused, so must the other, and hospitals must decline to treat all London children whose ailments have been selected by the London County Council as specially important. Again, if school children are to be refused treatment for certain parts of the body, are they to be accepted for other parts of the body? Is a child to be refused treatment for ringworm or eye defects, and to be accepted for enlarged glands or for rickets? And how far is this division of the body into diseases which are eligible and diseases which are not eligible to be carried? Very likely the London County Council will at times add another to their list of affections which they deem to be of importance; are the hospitals each time to revise their list of boycotted diseases?

The opposition of the Branch Council will result, if carried out, in this—that no London children shall be treated in a hospital out-patient department. And among other things, the hospitals, and especially the children's hospitals, would be deprived of any children out-patients for purposes of medical education.

If the hospitals refuse to treat the affections named by the London County Council, the alternative appears to be the establishment of municipal clinics. These will require large waiting rooms, as each child will be accompanied by a mother and often by other children, who cannot be left at home. Cases of infectious disease, especially when throat cases attend, will inevitably come to the clinics, and there must be isolation rooms. Some children will be unfit after operation to return home at once, and beds will soon be wanted. A pathologist and laboratory are essential, and a staff of clerks, nurses, and porters. The municipal clinics will be extensive and costly, and even if the London County Council does not soon add to its list of diseases (adenoids are already ready for nomination), and the hospitals inconsistently continue to treat some school children, the clinics will soon become municipal hospitals.

It is suggested that the profession will be benefited by this. Is it likely that more money will go into their pockets if the London County Council have to erect municipal buildings than if they pay grants to existing hospitals to be devoted to the expenses of the out-patient departments concerned, and which will provide salaries for qualified clinical assistants? I think not; and so far from the labours of the honorary staffs being increased, they will be lightened by such assistants. I venture to hope that the members of the hospital staffs to whom special appeal is made in the circular will not without full consideration decline to discuss with the London County Council their proposals. Although municipal clinics may be required in some districts, there is no sufficient reason why arrangements shall not be made by hospitals with the London County Council (at any rate, provisionally for a year or so,

after which the matter could be reconsidered) whereby school children shall continue to be treated by the hospitals to the advantage of the profession and of the public. —I am, etc.,

London, W., June 9th.

SIDNEY PHILLIPS.

"FACTS" AND "THEORY" REGARDING THE TREATMENT OF SEVERE ANAEMIAS.

SIR,—Your readers may be interested to hear that my so-called "theory" of infection, which the writer of a paper in your issue of June 5th (p. 1347) refers to, and attempts with imperfect success to describe in a few words, is going on very well, and has grown quite a strong young fellow, thanks to his original excellent constitution. He attains his majority this year, which is quite remarkable, considering that, being only a "theory" founded on twenty-five years' work, he ought to have been dead and buried long ago.

It may also interest them to know that the "facts" about successful treatment with bone marrow, which the writer describes and dwells upon with seeming satisfaction, are unfortunately in rather a sad way. For it happens to be known to me, although obviously not known to the writer of the paper, that both the "successful" cases which he refers to had relapsed, and one of them at least was dead some three to four weeks before he was recorded as cured! It was distinctly unfortunate that he died in the short interval of a month or two between the time of writing and the publication of the author's paper. It was truly "pernicious" on his part to do so.

But it only serves to illustrate what I have in a recent new work on these anaemias demonstrated from cover to cover—namely, that the hollow mockery of the so-called "facts" of etiology, clinical features and diagnosis associated with the name "pernicious," which for the past thirty to forty years have deluded the profession and made the poor patient's disease a terrible tragedy, follows the latter even into their graves. One to two years after they are dead; they are still reported on as wonderful examples of cures!

Now, Sir, what I have attempted to do is to deprive this astounding disease alike of its pernicious mystery and its pernicious name. That and a hundred and one other facts are involved in what my friendly detractors still continue to term to their own satisfaction a "theory," "contention," "hypothesis."

I therefore throw them out a challenge which they can, singly or collectively, meet as may seem good to them.

I notice in the literature of the past seven years or so a steadily increasing number of references to the improved prognosis of these anaemias and their greater amenability to treatment than formerly. My challenge is therefore the following: Will any observer or group of observers point to any single measure of treatment—other than those connected with, and suggested by, my work regarding the infective nature of these anaemias—which during this period differs in any form or degree from the measures previously adopted?

Even the writer who terms my work a "theory" states that certain of the measures—which he very inadequately describes—"should never be neglected." Why so, if they are only based on a "theory"? As a matter of fact, the treatment based on this "theory" is, as I know from scores of cases sent to me, and from information on every hand, being carried out in an increasing number of cases daily. What useful purpose, then, is served by terming it a "theory," thereby blinding the eyes alike of doctors and patients to its real nature and value, and perpetuating even in treatment the pernicious confusion which has characterized these diseases from first to last?—I am, etc.,

London, W., June 8th.

WILLIAM HUNTER.

SANITARY PROGRESS IN THE BRITISH WEST INDIES.

SIR,—I was very much interested in reading Sir Robert Boyce's account of recent sanitary progress in the West Indies published in your issue of June 5th, 1909. As long ago now as 1901 I made a similar visit for the London

School of Tropical Medicine to the same islands and British Guiana, including also St. Kitts, as the governor and inhabitants specially requested the Colonial Office that I should not omit them in my tour. Filial diseases and other mosquito-borne maladies were the objects of special study, opportunities being taken at the same time to instruct the populations of the different places in respect to mosquito prophylaxis. About this time Professor Ross was carrying out experiments for the destruction of *Anopheles* in Africa, and the Americans in Cuba had just proved the part *Stegomyia* played in the transmission of yellow fever, so that things were ripe for useful work.

Largely owing to the energy and interest which Sir Frederick Hodson, the Governor of Barbados, took in the subject, I followed out a plan of campaign very like that described by Sir Robert Boyce—namely, giving lectures to the medical profession, more popular ones to the laity, and a course of special lectures to the sanitary inspectors of the island. Examination of yards, special localities and breeding grounds were also carried out, and one specially interesting fact was soon discovered—namely, that there were no *Anopheles* mosquitos in Barbados. This coincided with the clinical experience of the physicians there—that there was no indigenous malaria amongst the population. It soon became evident that it was useless for a few individuals to destroy the common mosquitos found in houses if the general population was to remain apathetic, so I suggested to Sir Frederick the advisability of having a law passed to enforce their destruction, the penalty for not doing so being a fine, a similar procedure to that adopted by the Americans in Havana. The measure came up for discussion after I had left the island, and I believe was rejected; it is therefore specially interesting to hear that six years afterwards such a measure is actually in force.

I found little difficulty in persuading the medical men of the different places visited as to the part the mosquitos played in the spread of disease; it was the laity who were specially conservative and unprogressive, and even then perhaps things might have moved more quickly if the necessary funds had been available. There is little doubt that progress in mosquito destruction in some British Colonies is woefully behind that in American possessions (Havana, Colon, Panama, etc.), but still there is now an advance even in the West Indies; and one must be grateful for that. It would be a pity that the good work Sir Robert Boyce has helped to carry on should be allowed in any way to stand still or go back; and though perhaps a meeting of the British Medical Association in Trinidad or Jamaica will not take place, I should suggest that the Colonial Office or one of the tropical schools should send some one every three years or so to the West Indies to study the progress made, and to advise on further sanitary developments. Persuade the merchants that no mosquitos mean no yellow fever, and a great deal can be done.—I am, etc.,

London, W., June 5th.

GEORGE C. LOW.

SPINAL ANAESTHESIA.

SIR,—I trust you will allow me space to criticize briefly the announcement emanating from the London Hospital, with regard to the method of inducing analgesia by the intraspinal injection of stovaine, which appeared in the *Daily Mail* of June 3rd.

As a hospital surgeon, it appears to me, as it probably does to most of my professional brethren, that the action of the House Committee of the London Hospital in issuing any report on so purely scientific a matter as this, is at least very unusual. With every respect for the good intentions of that committee, one cannot help thinking that any such report should have come from the professional staff of the hospital and not from the members of the lay committee.

Quite apart from this question, however, there is another which is of much greater importance. The report, coming as it does from so influential a source as that of our largest London hospital, must in the eyes of the public at least inevitably bear the stamp of authority, and by suggestion lead that public to suppose that the conclusions arrived at (and with which I have no fault to find) are the outcome of the energetic work and the personal experience of the staff of this well-known hospital. But this I have reason to believe is by no means the case. On the

evidence of a member of the House Committee of the London Hospital, as well as from other sources, I am given to understand that the method has neither been accepted by the hospital authorities nor practised by the staff of the hospital to the extent which obtains in many other quarters, and certainly not to such an extent as to warrant the House Committee of the London Hospital taking a stand as an authority on the subject. In doing so they are unquestionably robbing University College Hospital of the just claim to be considered the first and foremost hospital in London to place this method on a sound and sure basis. At least two other hospitals—namely, the Seamen's Hospital, Greenwich, and the Hospital of the Royal Army Medical College, Millbank, have long been able to show results which the House Committee of the London Hospital would appear, at least by inference, to lay claim to. That the work done by the London Hospital is admirable, no one who knows anything of surgery will deny; but that its House Committee should lay claim to constitute itself an authority on the subject of spinal analgesia, is a matter which cannot be allowed to pass unchallenged. If the conclusions at which it has arrived are the result of work carried out in the wards of the London Hospital, it would have been more satisfactory and extremely interesting, if the statistical evidence on which the conclusions are founded had been given to the medical profession; if, on the other hand, these conclusions are drawn from the work done in other hospitals, would it not have been more courteous to these hospitals, and less misleading to the public, to have acknowledged the source of the information obtained?—I am, etc.,

London, W., June 7th.

LAWRIE MCGAVIN.

THE BRITISH MEDICAL BENEVOLENT FUND.

SIR,—Local secretaries of the British Medical Benevolent Fund confine their appeals for aid to their own districts and have intimate knowledge of the persons benefited by the charity administered by the central committee. A good many years have passed since I first took an active interest in the fund, and my experience of the generous methods of those who have carried on the work, in spite of indifference and financial difficulties, has been that the cases recommended have been relieved quietly and promptly. No doubt this is a common experience among local secretaries. I am moved to write to you to-day because I have received a letter from one of the beneficiaries of the fund which illustrates the operations of this most deserving charity. The case is only too common—a lady left with a family of young children almost unprovided for owing to the early death of her husband, who was in general practice of the more unremunerative kind. She is handicapped by cardiac troubles, and her life has been a record of strenuous toil. The fund has been her mainstay, a grant of £12 a year, repeated year by year, has relieved her of anxieties about house rent, and she has striven for the education of her children with that and other aid. It is a small grant, strictly limited by the narrow means at the disposal of the committee, yet she says:

My experience of life during the last ten years has been so hard that I feel almost too tired to write about it. I don't understand how anyone could hesitate in helping such a fund, especially educated men who know how many benefit from it, and what a help it is to those who many a time do not know how to get a decent meal.

I might also cite a case of suffering prolonged through many years—a practitioner who had saved some little money when he was rendered useless by paralysis. When my attention was directed to him he was living in the humblest manner at an expenditure of 6s. a week. His bodily state was deplorable, and he was torn by anxiety. His savings were almost exhausted after some twenty years of invalidism and incapacity, and he lived in dread of an appeal to the parish. I was enabled to assure him that the fund would undertake to provide for him as soon as his money was exhausted. His mind was relieved, his gratitude was painful to witness, until death relieved him from his "mattress grave."

I know very well that there are only too many of the less fortunate doctors who are quite unable to subscribe to the British Medical Benevolent Fund—one of them, indeed, lately said, "You have no idea what half a

crown means to me just now." And I know quite as well that there are very few whose income reaches a comfortable competency even in these days of great wealth; but I am impelled to add that the apathy of those who are unconcerned by the necessities of silent and suffering poorer brethren is shameful to members of a liberal profession. We, who endeavour to direct their attention to the limited resources of the fund and the urgency of the claims made upon it do not ask for great sacrifices or notable contributions: we merely plead for the steady annual subscription of moderate sums. If every medical man on the *Register* gave 5s. the result would be some £10,000 for yearly distribution. The accounts of the grant department for 1907 showed receipts barely reaching £1,700. For the credit of the profession, for the necessities of our poor, it is not enough.—I am, etc.,

Perth, June 7th.

A. R. URQUHART.

"THE DOCTOR AS A VICARIOUS PHILANTHROPIST."

SIR,—I fear Dr. Wishart Kerr's suggestion will not commend itself to the bulk of the profession. Not many of us would have the fortitude to risk the "cursing of a hostile and threatening crowd" outside our surgeries (which are generally also our homes), and indeed I cannot but think that we should fall in our own estimation as well as in that of the crowd. In such a case as Dr. Kerr describes, it seems almost our duty to give our services gratuitously; the patient cannot guarantee remuneration, and there is no onus on any of the crowd to do so. Our assistance, skilled though it is, is but what we owe of humanity to the unfortunate victim: moreover such cases (street accidents) are rare, perhaps two per annum to each medical man, and entail no serious loss of income or derangement of business.

Night calls are in another category; they are demanded by responsible persons—the patient himself or his friends—and entail a serious disturbance of rest and health; but even they would be better dealt with on another basis than that of pecuniary reward. My custom is to refuse all night calls except from my own patients. I have no "red lamp," as I wish nobody to find me at night except those who can do so without a directing light. Night calls are made on a doctor by strangers generally because they fear their own doctor (to whom they already owe money) will not go; and my answer to such is that my own patients give me all the night work of which I am physically capable, and that theirs is the responsibility and duty of keeping on good terms with their doctors.

I commend this plan to my professional brethren. Night calls (even if paid for) are a poor source of income. Never admit any question of a fee, and one's position will be a great deal pleasanter in the event of the matter becoming public.—I am, etc.,

Bristol, June 5th.

HARRY GREY.

MANCHESTER (WEST) DIVISION.

SIR,—In the account of the proceedings of the General Medical Council, published in the *SUPPLEMENT* to the *BRITISH MEDICAL JOURNAL* of June 5th, certain assertions appear which imply that the Manchester (West) Division has dealt with the complaint against Dr. C. W. Brown, a member of the Association, residing in the Division.

As Honorary Secretary of the Division, I beg to state that no complaint against that gentleman has ever been received by me, and that neither the Division nor its Executive Committee has at any time discussed this case or taken any action whatever in connexion therewith.—I am, etc.,

J. SKARDON PROWSE,

Manchester, June 8th.

Hon. Sec., Manchester (West) Division.

SIR,—In justice to the Honorary Secretary of the West Manchester Division, may I ask you to correct a self-evident error which has crept into the summary of my evidence before the General Medical Council on May 26th last?

From the printed report, it would appear that the Honorary Secretary had informed me that the complaint of Dr. Paterson had been received and considered by the West Manchester Division; this is incorrect; the evidence given by me was to the effect that the Honorary Secretary had

informed me that the West Manchester Division had *not* considered, much less decided to prosecute, a charge against Dr. Brown, and I further supported this statement by pointing out that, by the rules of the Division itself, as no notice of complaint had been sent to the person accused, the Division *could not* have considered the complaint, and much less could they have taken a vote on it!

This evidence was given by me in reply to questions asked by Mr. Bodkin with the object of rebutting the opening statement of the prosecution that the complaint had been considered by the West Manchester Division, and was now brought before the General Medical Council by the unanimous request of that Division; and this evidence was made further use of by Mr. Bodkin for this purpose in his opening address on the following day.—I am, etc.,

Manchester, June 8th.

UNIVERSITY OF CAMBRIDGE.

Prizes in Botany and Zoology.

THE Vice-Chancellor has received an offer from Mr. Francis G. Smart to give £600 to found an annual prize for Botany and Zoology respectively.

Degrees.

The following degrees were conferred on June 3rd:

M.D.—M. A. Cassidy, Cla.; C. W. Ponder, Esq.; R. N. Hart, Esq.
M.B.—B.C.—K. M. Walker, Esq. and Cai.

UNIVERSITY OF LONDON.

Meeting of the Senate.

A MEETING of the Senate was held on May 19th.

Recognition of Teacher.

Dr. William H. Willcox has been recognized as a teacher of forensic medicine at St. Mary's Hospital Medical School.

Amendment of Regulations.

It was resolved that the following should be substituted for Section 17 of the Regulations as to approved courses of study (Red Book, September, 1903, p. 9):

A student who has matriculated in January, or has been exempted from matriculation under Statute 116 as from January, may be registered as an internal student as from the date of the beginning of his course of study, provided that such date be not anterior by more than four months to the date of the first day of the matriculation examination which he passed, or in respect of which he was registered, and that the present regulation shall not apply to students who matriculated or were exempted from matriculation before January, 1906.

Brown Animal Sanatory Institution.

Mr. F. W. Twort, M.R.C.S., L.R.C.P., has been appointed superintendent of the Brown Animal Sanatory Institution for three years from June 1st, vice Professor T. G. Brodie, M.D., F.R.S., resigned.

Mr. Malcolm Allan, M.R.C.V.S., has been reappointed Veterinary Assistant for the coming year.

The annual report of the Committee of the institution stated that the number of cases treated last year as out-patients was 6,264, and as in-patients 699.

Amendment of the Scholarships Regulations.

It was resolved that the following amendments be made in the scholarships regulations (the references are to the *Calendar*, 1908-9):

(a) On page 264 insert the following:

11. The term "matriculated students" as used in these regulations includes all students who are registered as matriculated students of the university by reason of having passed the matriculation examination of the University of London either in its ordinary form or in the form of the school examination (matriculation or higher standard) conducted by the university for its school-leaving certificate, or an examination accepted in lieu of the matriculation examination under the terms of the statutes, Section 116.

(b) On page 263, Regulation 5, line 3, for "with the receipt for," substitute "before the payment of."

(c) On page 265, line 1, for "paragraph" substitute "paragraphs."

Instruction in Practical Midwifery for the M.B., B.S. Examination for Internal and External Students.

In connexion with the recommendation of the Faculty of Medicine suggesting that the teaching of practical midwifery in the wards of a lying-in hospital or lying-in ward of a general hospital should be made compulsory as soon as practicable which the Senate on May 13th, 1908, directed to be sent to the medical schools of the universities and other medical schools

from which certificates were received, the Senate on May 19th, 1909, adopted the following resolution:

That, in order to allow the medical schools of the University and the other medical schools from which certificates are received for the M.B., B.S. examinations to take time to complete the necessary arrangements for the teaching of practical midwifery in the wards of a lying-in hospital or the lying-in ward of a general hospital, further action in connexion with the resolution contained in Minute 2333 of May 13th, 1908, be postponed for twelve months from the present date; and that the schools in question be informed accordingly.

B.Sc. (Honours) Degree in Human Anatomy and Morphology.

It was resolved that for internal students the following be substituted for paragraph A (Red Book, September, 1908, p. 207).

A. Candidates who have passed the second examination for medical degrees as internal students. Such candidates must pursue a further approved course of study extending over one year, and must have attended . . . (The rest of the paragraph as at present.)

For internal and external students: That for the words (Red Book, September, 1908, p. 209; Blue Book, p. 511: Subsidiary subjects, Physiology, Zoology, be substituted the following:

Candidates for the B.Sc. (Honours) degree in Human Anatomy and Morphology will not be required to present any subsidiary subject.

The Senate.

Dr. E. G. G. Little (Convocation, Medicine), Mr. H. H. Clutton (Royal College of Surgeons of England), and Professor E. H. Starling, F.R.S. (Faculty of Medicine) have been re-appointed to the Senate, while Sir William H. Allchin succeeds Dr. P. Pye-Smith as the representative of the Royal College of Physicians of London on the Senate.

Appointment of Representative.

Dr. E. G. G. Little has been appointed the Representative of the University at the Health Congress to be held at Leeds in July, 1909.

Boards of Examiners for Medical Degrees.

The following have been elected chairmen in the subjects indicated for the first and second examinations for medical degrees for internal and external students: *Anatomy*, Professor J. Symington, M.D., Ch.M., F.R.S.; *Chemistry*, Mr. J. A. Gardner, M.A., F.I.C., F.C.S.; *Zoology*, Mr. F. E. Beddard, M.A., F.R.S.; *Pharmacology*, Professor A. E. Cushman, M.D., C.M., M.A., F.R.S.; *Physics*, Mr. A. W. Porter, B.S.; *Physiology*, Professor G. A. Buckmaster, M.D., B.Ch., M.A., D.P.H.

Advanced Lectures in Physiology.

Professor E. H. Starling's course of lectures on recent advances in physiology has been postponed until next term.

University of London Lodge of Freemasons.

Dr. Robert Henry Cole has been elected Master for the ensuing year.

London (Royal Free Hospital) School of Medicine for Women.

The following scholarships will be awarded on the result of the Intercollegiate Scholarships Board examination to be held on September 21st and the following days:

1. The School Scholarship, value £30 a year for one year, open only to candidates who have passed a recognized preliminary examination and are not holding any other scholarship. The successful candidate will be required to enter at once upon a full course of medical study at the school. Students who have been at the school only one term can also compete for this scholarship.

2. St. Dunstan's Medical Exhibition, value £60 a year for three or five years. Candidates must be: (1) Not more than 20 years of age on June 1st, 1909. (2) Resident in the Metropolitan Police district area for the past three years or longer (this area includes a large district round London). (3) Matriculated students of the University of London. (4) In the opinion of the governors in need of such an exhibition for the prosecution of their medical studies.

The Fanny Butler Scholarship, value £14 10s. a year for four years, is open only to candidates willing to practise in connexion with the Church of England Zenana Missionary Society, 27, Chancery Lane, W.C.

THE VICTORIA UNIVERSITY OF MANCHESTER.

THE CHAIR OF ANATOMY.

ALL medical students past and present who have had the opportunity of working under Professor Young at Owens College will most sincerely regret that ill-health has compelled him to retire from the Professorship of Anatomy at the Manchester University.

* Students who have passed in Anatomy and Physiology at the second examination for medical degrees as internal students will be allowed to submit for the B.Sc. (Honours) degree in Human Anatomy and Morphology a course of study extending over one academic year from the date at which they passed in the subjects enumerated above, but in no case shall they be allowed to present themselves for such B.Sc. (Honours) examination unless they shall have passed the second examination for medical degrees (or the intermediate examination in science subject to the conditions given under B. below).

The post has now been filled by the appointment of Mr. Grafton Elliot Smith, Professor of Anatomy in the Government School of Medicine at Cairo. Professor Smith graduated at the University of Sydney in 1893, and obtained the degree of M.D. in 1895 with first class honours and the university medal. After acting as house-physician and house-surgeon in the Royal Prince Alfred Hospital of Sydney, he was demonstrator of anatomy for two years under Professor J. T. Wilson. He obtained a travelling Fellowship of the University of Sydney, and proceeded to Cambridge, where he took the degree of M.A. in 1902. He was elected to a Fellowship of St. John's College, and was appointed Demonstrator of Anatomy. Later he was appointed Professor of Anatomy in the Government School of Medicine at Cairo. He has done a considerable amount of original work in embryology, anthropology, and surgical applied anatomy, and was director of the archaeological survey of Nubia. He was selected in 1905 to make the official catalogue of royal mummies at the Cairo museum. He is author of *The Brain in Reptiles and Mammals*, and is perhaps best known for his researches on the anatomy of the brain and nervous system.

UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.

VISCOUNT TREDEGAR, who, since its establishment has frequently given substantial proof of his interest in the college, just expressed his intention of contributing another £5,000 towards the new college fund; this brings his donations towards the building fund to £12,500. His first was a sum of £2,500, given on the occasion of the first effort made to establish a building fund. Viscount Tredegar is the largest of all the private donors. The Drapers' Company of London has contributed £16,000 towards the new library; Mr. Harry Webb has also given £500 towards the building fund.

ROYAL COLLEGE OF SURGEONS.

THE COUNCIL ELECTION.

The number of candidates for election to the council now amounts to seven, and the list is complete, as no more applications can be received. The three retiring members of council—Sir Watson Cheyne, Mr. Mayo Robson, and Mr. Clement Lucas—seek re-election. There remain four candidates. The senior of the four as a Fellow of the College is Mr. Harrison Cripps (Fellow, June, 1875; Member, July, 1872); the second is Mr. C. H. Ballance, M.V.O. (Fellow, June, 1882; Member, July, 1879); the third, Dr. Bland-Sutton (Fellow, June, 1884; Member, July, 1882); and the fourth, senior to Mr. Bland-Sutton as a Member but junior as a Fellow, is Mr. Walter Hamilton Hylton Jessop (Fellow, December, 1884; Member, 1880).

Our annual analysis of the council, including the proportional representation of medical schools and provincial hospitals, will be found in the JOURNAL for May 22nd, p. 1272. The contest—as all the three retiring members seek re-election, and all the four candidates well-known surgeons—will be of unusual interest. Mr. Harrison Cripps has twice served on the council as a substitute member, and distinguished himself as Chairman of the Finance Committee. Mr. Ballance, M.V.O., has won wide renown as an authority on the surgery of the brain and the great arteries. Mr. Bland-Sutton is a leader in gynaecological surgery, and Mr. Jessop is Ophthalmic Surgeon to St. Bartholomew's Hospital.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE sixty-sixth annual meeting of the Royal College of Surgeons in Ireland was held on June 5th, when the chair was occupied by Mr. John Lentaigne, the President.

Finance.

The Auditor's certificate for the year showed that the receipts for the year amounted to £4,174 3s. 6d., leaving a balance due to bank at close of year of £121 1s. 9d. The general investment account shows a sum of £9,469 18s. 11d., while there are the usual sums invested for prizes.

Diplomas.

Nineteen candidates were admitted to the Fellowship. Forty-seven candidates received the Conjoint Diplomas in Medicine, Surgery, and Midwifery of the Royal Colleges of Physicians and Surgeons. One candidate, a registered practitioner, was admitted a Licentiate. Twenty-seven candidates received the Conjoint Diploma in Public Health of the Royal Colleges of Physicians and Surgeons. Sixteen candidates received the Licence in Dental Surgery. Seventy candidates having passed the Conjoint Preliminary Examination with the Royal College of Physicians received certificates.

Physical Education.

It was moved by Dr. J. B. Story, and carried unanimously:

That having regard to the importance of physical education, and the neglect with which it has hitherto been treated in Ireland, it is desirable that representatives of the medical profession, as such, be appointed upon the Board of National Education and upon the Board of Intermediate Education.

Election of Officers.

At a meeting of the Fellows held on June 7th, the following were elected officers for the ensuing year: President, John

Lentaigne; Vice-President, Robert H. Woods; Secretary of the College, Sir Charles A. Cameron, C.B.; Council, Sir Henry R. Swanzy, William Stoker, Sir Charles Alexander Cameron, C.B., John B. Story, Sir Charles B. Ball, Sir Thomas Myles, Sir Arthur Chance, Richard D. Puresoy, Sir Lambert H. Ormsby, Henry G. Sherlock, R. Bolton McCausland, R. Lane-Joynt, William Taylor, Edward H. Taylor, G. Jameson Johnston, R. Charles B. Maunsell, William Ireland Wheeler, D. Edgar Flinn, Thomas E. Gordon.

CONJOINT BOARD IN IRELAND.

THE following candidates have been approved at the examination:

D.P.H. Parts I and II.—W. W. Browne, Captain, R.A.M.C. (with Honours); R. F. O'T. Dickinson, Lieutenant, R.A.M.C.; B. D. Gibson; D. J. O'Connor; N. D. Walker, Captain, R.A.M.C.

Medico-Legal.

SLANDER ACTION AGAINST A MEDICAL MAN.

JUDGMENT has been given in the Falkirk Sheriff Court against Dr. Gardner in an action brought against him by a nurse. This nurse averred that Dr. Gardner had said of her that she was no nurse at all, that no respectable persons in Falkirk would let her into their house, and she had no right to wear uniform. She claimed £250 in the name of damages. The pursuer also stated that Dr. Gardner had said of her that she was a dangerous woman, that the condition her children were in was owing to her drinking, and if the worst came to the worst he could prove that she was a dirty woman. Dr. Gardner denied having slandered Nurse McLachlan, and pleaded that in any case what he said was privileged in view of his position of medical attendant to the persons to whom the statements were made. Sheriff Mowatt, in his judgement, finds the first of the statements not proved, but finds it proved that the defender said of the pursuer that she took drink, and that the condition her children were in was owing to her drinking. He also finds that the defendant said of the pursuer that she was a dangerous woman, and that he would prove she was dirty, and that on neither occasion was the statement in any way privileged. The damages were assessed at £10, with expenses.

Public Health

AND

POOR LAW MEDICAL SERVICES.

LOCAL GOVERNMENT BOARD IN ENGLAND.

SCIENTIFIC INVESTIGATION.

IN connexion with the annual grant voted by Parliament in aid of scientific investigations concerning the causes and processes of disease, Mr. Burns, the President of the Local Government Board, has authorized the following special researches:

1. A continuation of the investigation into protracted and recurrent infection in enteric fever, by Dr. Theodore Thomson, Medical Inspector of the Board, in conjunction with Dr. Ledingham of the Lister Institute.
2. A continuation of the investigation into protracted and recurrent infection in diphtheria, by Dr. Theodore Thomson and Dr. C. J. Thomas.
3. A continuation of the investigation into flies as carriers of infection, by Dr. Monckton Copeman, Medical Inspector of the Board, and by Professor Nuttall of Cambridge.
4. A continuation of Dr. Andrews's investigation on the presence of sewage bacteria in sewer air, with a view to ascertaining their number and the distance they can be carried by air currents. Also a continuation of Dr. Andrews's investigation into the part played by changes in bone marrow in the defensive mechanism of the body against infection.
5. A continuation of Dr. Savage's investigations on the bacterial measurement of milk pollution, and on the presence of the Gaertner group of bacilli in prepared meats and allied foods.
6. An investigation into the chemical and physical changes undergone by milk as the result of infection by bacteria, and into the relation of the process to epidemic diarrhoea, by Dr. H. A. Schöberg, Lecturer in Bacteriology in University College, Cardiff, and Bacteriologist to the Glamorgan and Cardiff Councils; and Mr. Wallis, Lecturer in Physiology, University College, Cardiff.
7. An investigation of the records of charitable lying-in hospitals as to the nutrition of the mother and other factors influencing the vitality of infants and their progress in the first fourteen days of life, by Dr. Darwell Smith, Physician to the British Lying-in Hospital.
8. An investigation into the occurrence and importance, in relation to treatment, of mixed infections in pulmonary tuberculosis, by Dr. Inman, Pathologist to the Brompton Hospital for Consumption.
9. An investigation on the relative importance of certain types of body cells in defence against the tubercle bacillus, and the effect of tuberculin and other remedial agents on their activities, by Dr. J. Miller, Pathologist to the General Hospital, Birmingham.

MEDICAL INSPECTION OF SCHOOL CHILDREN.

THE following document has been sent by the Honorary Secretary of the Winchester Division, with a request that it should be published in the JOURNAL:

The Court of Governors of the Royal Hants County Hospital have had their attention called to the recent provisions for Medical Inspection of Children.

It would seem that provision is now made for the Medical Examination of all Children under Section 13, Subsection B, of the Education Act (Administrative Provisions), 1907, the duty of providing for such Medical Inspection is placed upon the local Education Authority. In the event of Children being certified to require medical care and attention, the Court of Governors consider it probable that it may become the custom to send many such cases to the special departments of the Hospital for treatment. It would seem that this idea has probably occurred to the Board of Education, inasmuch as Circular 596, dated 17th August, 1908, addressed to the Local Education Authorities, contains suggestions for contributions to Hospitals, Infirmarys, Dispensaries, etc. (Clause 78), and making it "permissible to include among the conditions of contribution a provision allocating a reasonable remuneration to the Medical Men working for such Institutions."

The Court of Governors feel, after full consideration, that this latter proposal would be undesirable, and, greatly though funds are needed, could not be entertained. Any such scheme of payment would alter the whole of the existing arrangements and cause the Hospital to be worked on totally different lines and in a way which the Court of Governors could not approve. The Medical Staff attached to the Hospital give gratuitously their services to the Hospital Authorities, and the public owe them a great debt of gratitude. The Court of Governors feel that, having regard to the heavy demands that are made upon their Staff, they would not be justified in allowing general treatment of the numerous cases that must arise as the result of the Medical Inspection provided by the Act referred to, and they desire to suggest that the Local Education Authority should, before these questions arise, proceed to make arrangements for the discharge of these duties by the medical men in their respective districts, which they have ample powers to do.

The Hospital will not object to taking, as at present, urgency cases, or other cases requiring, in the opinion of a responsible medical man, such care and attention as only the Hospital can supply.

The Court of Governors need to bring this matter before the Local Education Authority in order to allow ample time for provision to be made and to prevent any misunderstanding or difficulty arising.

TUBERCULOUS MEAT.

THE Corporation of the City of London has issued a circular for the information of meat salesmen within the City who, it is recognized, are anxious and willing to do anything in their power in the interests of public health and legitimate trading to prevent unsound meat being offered for sale. The circular states that for many years the Corporation has instituted legal proceedings, resulting in many instances in the infliction of heavy fines or terms of imprisonment against farmers, butchers, and other persons for sending diseased or unwholesome meat into the City markets, or for exposing such meat for sale. In some instances the offence may have been due to gross carelessness or even ignorance of the symptoms of disease in the living animal, or of the appearance of unsound carcasses after slaughter, and the object of the circular is to make public a memorandum by Dr. Collingridge, the Medical Officer of Health of the City, pointing out the signs of tuberculosis in the carcass and organs, and another by Mr. James King, M.R.C.V.S., Veterinary Inspector to the Corporation, on the symptoms in the living animals.

DRAINAGE OF LOW-LYING TOWN.

M.O.H.—Drainage of a small town where there is practically no fall presents special difficulties. At Chester, where sewage purification works were carried out by Major Hector Tulloch, C.B., R.E., the sewage has all to be pumped up before it can be purified, for the reason that it reaches the outfall 8 or 10 ft. below the level of the ground, which for miles on both sides is below the level of the river, and would be flooded but for embankments. It is pumped by suction gas engines and centrifugal pumps. The gas is made out of anthracite coal, and at the price of 24s. or 20s. a ton of coal the makers will now guarantee from 8 to 10-h.p. an hour for a penny. Centrifugal pumps are used, because any form of plunger pump is out of the question for sewage in which there is so much hard material like gravel, sand, etc., which wear out the surfaces of the brass plunger cylinders.

DIPHTHERIA: PERIOD OF QUARANTINE FOR CARRIER CONTACTS.

S. T. B.—It is not by any means the universal practice of medical officers of health to insist upon three negative results after the bacteriological examination of material taken from the throats of diphtheria patients or of contact carriers of the disease. There is no doubt that it would be a great advantage if the practice were universal, and also if the nasal passages were swabbed as well as the throat.

OFFICIAL TREATMENT OF DIPHTHERIA.

ULULA.—It is not usual, nor is it desirable, for a patient to be removed to an isolation hospital without any reference to the medical attendant, unless in exceptionally urgent circumstances. For the charge nurse of an isolation hospital to inject antitoxin (4,000 units) as a matter of routine in all cases of diphtheria admitted to a hospital is a practice to be deprecated. The injection should be made by the medical man in charge of the patient.

THE BACTERIOLOGICAL DIAGNOSIS OF DIPHTHERIA.

DR. EDWARD CARNALL, D.P.H. (Newton Abbot) writes:

The number of cases admitted into provincial isolation hospitals of late years as diphtheria, when compared as regards population with the number of cases notified in a central London district, suggests the question whether the swab is to be relied on as a correct means of diagnosis.

In reading the reports of large central London institutions where patients are visited at their own homes and are treated at the dispensary one finds that out of a total of 35,455 patients only 25 cases of diphtheria have been sent to the Metropolitan Asylums Board hospitals during the past eight years. It cannot be said that the conditions under which this large number of people live is better or more hygienic than in small urban and rural districts; in fact, if any one visited some of the streets and courts of a London district they would be rather surprised to see the conditions under which some of the people live or exist.

As we all know, the throat is a part of the body most susceptible to influences (not of necessity sewer gases), such as changes of weather, foul air, state of our general health, and catarrhal conditions; it is easy to understand the number of so-called sore throats which fall to the lot of a dispensary doctor. As regards the swab patients after a stay of twenty-one days or more in hospital will be returned as positive, when no sign whatever exists that the patient is or has been suffering from diphtheria. It is also noticed that children with enlarged tonsils, if treated locally and generally, will be returned also positive, and it seems to be impossible to obtain a negative result from such cases. The only reason why such cases are sent to the hospital is the swab return. Nothing is seen in the throat, nor has the patient even developed any symptoms of the disease. But the fact remains that all those cases after removal to the hospital, whatever the condition of the throat—there may be patches on tonsils or fauces—improve rapidly whether treated or not, which points to their real nature. I have also noticed that cases of what appears to be genuine diphtheria always return a negative result after the allotted stay in hospital. Whether we should admit cases to the acute wards of hospitals solely on the swab result is doubtful; for no doubt children have been admitted on swab evidence alone and developed diphtheria after admission, but have been saved by the prompt antitoxin injection.

Obituary.

WE regret to note the death on June 1st in St. George's Hospital of Mr. HENRY KAY RAMSDEN, M.B., B.Ch.Manch., of 102, Sloane Street, after a long and trying illness, borne with great fortitude. He died at the early age of 42 years the victim of a malignant growth in the lungs. He was one of four brothers, all members of the same profession, and was the third son of the late Dr. W. H. F. Ramsden, of Dobcross, Saddleworth, Yorkshire, to whose memory in 1900 the people of the district erected a fountain "for his devoted services to the people of Saddleworth," on which is inscribed a quotation from Leigh Hunt's "Abou Ben Adhem":

Write me as one that loves his fellow men.

The same words might fitly be chosen to characterize the son. As illustrating his courage and humanity the following incident is worthy of record. While surgeon to a certain workhouse infirmary he had ordered a generous meat diet for some of the inmates for whose recovery he thought it specially necessary. The guardians declining to supply it, in spite of his urgent representations, their surgeon ordered it at his own expense from a neighbouring hotel,

and every day, accompanied by the cook bearing a large joint, walked through the streets from the hotel to the workhouse. These "meat-bearings" quickly developed into large processions of indignant sympathizers, and the guardians found themselves obliged to give way, and it is not surprising to learn that their surgeon had no further difficulty in getting his orders carried out. Mr. Ramsden had served as Civil Surgeon in the Boer war, and was Surgeon-Captain in the 2nd Battalion of the City of London Rifles. He was an ardent Freemason and a member of the Chelsea Borough Council.

Mr. GEORGE HENRY HAMES, who died on May 28th, at his residence, 11, Park Lane, was a well-known practitioner in the West End of London. He was a native of Lincolnshire. He joined the medical school of St. Bartholomew's Hospital in 1871, and distinguished himself as a student, winning several prizes. He obtained the diploma of M.R.C.S. in 1875, and that of F.R.C.S. in 1878. He was House-Surgeon to Sir William Savory; he also served a term of office as House-Physician. After quitting these house-staff appointments he attached himself to several other hospitals and dispensaries for a few years; but although he was distinguished as a good junior officer in all the appointments that he held, he decided early in life to devote himself to general practice, for which he proved eminently qualified.

Dr. CHARLES MARSHALL KEMPE, of Shoreham, died at his residence in that town on May 23rd. He had reached his 70th year, but, having regard to the fact that he was constantly to be seen about the town, and appeared to be in good health, his death after an illness of a day or two was the cause of much surprise as well as of the deepest regret. Dr. Kempe, a Cornishman by birth, and a student of St. Thomas's Hospital, became M.R.C.S. in 1861 and L.S.A. in 1863, and had long resided in Shoreham, where his life was one of great activity both in professional and non-professional connexions, and of marked public utility. On the professional side, in addition to private practice, he held at one time and another a large number of appointments. For some thirty years he was Medical Officer of Health for Shoreham, and a Medical Officer to the Steyning Board of Guardians. He was also a Medical Officer of Health to the Port Sanitary Authority, and Medical Officer to the Admiralty, to the Railway, and to the Order of Foresters. How fully he satisfied public expectations in these connexions is shown by his receipt of two illuminated addresses—one from the Shoreham District Council, the other from the local court of the Ancient Order of Foresters. The part he played in the local public life of the district was equally active. When the old School Board was in existence he was its Chairman for five years, and on its abolition he became Chairman of the local Education Authority. A zealous Freemason, he was a Past Master of the St. Mary of the Harbour Lodge, and one of the founders of the Duke of Richmond Lodge. He also took a leading part in the establishment of a soup kitchen in the town, and devoted a good deal of time to church affairs. He was often to be seen at public meetings in support of the Conservative cause, and was an excellent and popular speaker. He retired from practice some two years ago, but continued to co-operate in public affairs, and was this spring elected to a seat on the urban district council. Apart, therefore, from his attractive personal qualities, he must inevitably be greatly missed in the locality. He died on the Sunday preceding Empire Day, and as a mark of respect to his memory certain public proceedings in connexion with that festival were abandoned. Dr. Kempe was married, and leaves a family of three sons and three daughters.

THE London Spectacle Mission is stated, in its sixteenth annual report, to have received last year 2,915 applications for assistance. The society does not assist any one under the age of 25, its main object being to benefit old people of the poorer classes suffering from presbyopia. It was founded in the year 1886 by Dr. E. J. Waring, C.I.E., a retired medical officer of H.M. India Army, and until his death, in 1891, the mission was carried on at his sole expense. The honorary secretary is Miss C. Waring, 197, Sutherland Avenue.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL. The offices of the British Medical Association and of the British Medical Journal are at 429, Strand, London.

Communications respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

IS Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

S. B. W. asks for statistics as to the comparative amount of food, in general or detail, consumed by the United Kingdom and the Continental countries. He also desires to ascertain the relative amounts for Ireland and Great Britain.

HERPES PREPUTIALIS.

P. D. asks for advice in the treatment of chronic herpes preputialis in a patient who has suffered for the past two years. It comes on very badly about every three months, and remains from two to three weeks; it has recently spread to the glans. Various kinds of local applications have been tried; also constitutional treatment for rheumatic gout, but without success.

THE BRONCHOSCOPE.

DR. CHARLES W. CHURMAN (London). We ask for experience as to the value of the bronchoscope in the diagnosis of intrathoracic tumours in the early stage—that is, before they can be recognized by other methods, and whether any serious consequences such as hæmorrhage have been known to follow the use of the instrument.

PENDULOUS EAR.

W. M. B. asks for advice as to any means, mechanical or operative, of correcting the following defect: The patient is a baby 5 months old, whose right ear in its upper half is pendulous over the lower half. The cartilage at birth was found to have been displaced from the upper part of helix and antehelix to the skin in front of the ear over the zygoma. The ear after birth was strapped to the head with adhesive plaster, but no improvement ensued.

INCOME TAX.

E. C. B. has for many years made a correct income tax return for himself and partners. He has now received a request from the assessor or surveyor for certified copies of the partnership accounts for each of the past three years. Our correspondent has no certified accounts, no accountant being employed. He asks whether the Commissioners have power to make their demand, and what line of action should be taken.

* * On the first point we refer our correspondent to an answer given to "E. M. C." in the BRITISH MEDICAL JOURNAL for April 24th last, page 1043, where the question is fully answered. For the reasons there stated it will save trouble to "E. C. B." if he furnishes the accounts asked for, when the liability will be agreed to by the surveyor according to the results shown, with little or no difficulty. If an accountant is not employed the fact should be stated, when the surveyor will doubtless accept accounts signed by our correspondent as sufficient for his purposes.

ANSWERS.

APHONASIA.—We cannot depart from the rule against publishing anonymous communications. The name of the writer, however, need not necessarily be published.

DISAPPEARANCE OF MALARIA FROM ENGLAND.

"5814."—No complete satisfactory explanation has ever been offered of the disappearance of malaria from England. One suggestion is that many of the so-called cases were not really malaria at all, but on the other hand, provided that the weather is warm enough, there is no reason why it should not occur, as in many districts *Anopheles maculipennis* abounds. On the whole, however, this insect in England does not seem to bite readily, though, of course, it does so further south—in Italy, Spain, etc., where it is the chief propagator of the disease. Drainage can only have played a subsidiary part as it has certainly not stamped out all the mosquitoes. The requisites for the case to appear are, of course, the following: (a) An individual with gametes in his blood. (b) The *Anopheles* to bite and so become infected. (c) A sufficiently high atmospheric temperature for the development to take place in the tissues of the insect. This latter condition would probably only be fulfilled in England in late July and August, so that the season is very limited in its possibilities.

LETTERS, NOTES, ETC.

LYNN THOMAS AND SKRYEME FUND.

MR. WILLIAM SHEEN, M.S., F.R.C.S. (2, St. Andrew's Crescent, Cardiff), Honorary Secretary of this Fund, desires to acknowledge the following subscriptions:

Twenty-fourth List of Subscriptions.

J. Harris Jones, Maesteg	... £1 10 0
S. P. Francis, Brecon	... 0 10 6

AN APPEAL.

THE following further subscriptions are acknowledged by Sir John W. Moore and Sir Charles Cameron in response to the appeal signed by the Presidents of the two Royal Colleges in Dublin on behalf of a medical practitioner in Dublin who, through no fault of his own, is in distressed circumstances. The appeal was published in the JOURNAL of May 15th, p. 1211:

	£	s.	d.
Amount already acknowledged	22 19 0

ANSWERING LETTERS.

A GRADUATE OF FIFTY YEARS' STANDING writes to complain that the younger members of our calling are now in the habit of not answering letters addressed to them, to the great annoyance and vexation as well as inconvenience of their correspondents. "I have written," he says, "to two of the younger members of the profession within the last few weeks, and my letter, though undoubtedly calling for a reply, remains unnoticed. This has occurred to me now so frequently that I beg you will allow me to publicly protest, through the medium of your influential JOURNAL, against such an ungentlemanly practice."

QUININE IN SYPHILIS.

J. L. L. writes: Your correspondent, "T. A. P." (BRITISH MEDICAL JOURNAL, page 1276), is not wrong in assuming that quinine may exert a similar effect on the *Syphilis chancroide pallida* that it does on the malarial parasites, because experience has shown that quinine has a most beneficial action in syphilis, especially when combined with mercury. If "T. A. P." will refer to Whittall's *Dictionary of Treatment*, 4th edition, 1902, page 918, he will find there the following prescription:

R. Hydrag. c. creta...	gr. j
Quin. sulph.	gr. jss
Ext. opii	gr. j
Ext. quassiae	ss
Fiats pil.	Mitte xxxvi ter.	Sumat i ter in die p.c.	

This combination, or modifications of it, I have used for seventeen years, and I know that quinine was used in combination with blue pill long before that. As "T. A. P." suggests, the absence of anaemia and cachexia under this treatment is most striking.

MEDICAL GOLFING SOCIETY.

THE annual tournament of the Medical Golfing Society will be held at Burnham Beeches Golf Club on Thursday, June 24th. Play will be eighteen holes match play c. Bogey under handicap. There will be three prizes in each division: handicaps 12 and under, and handicaps over 12. The Henry Morris challenge cup and the Medical Golfing Society's gold medal will be competed for. There will also be a foursome sweepstake in the afternoon. Any person on the *Medical* or the *Dental Register* can join on payment of the annual subscription (4s.), which includes entrance to the tournament. Entries, accompanied by subscription and giving lowest handicap, should be sent to L. Elliot Greasy, 35, Weymouth Street, London, W., on or before Monday, June 21st. Conveyances will meet trains at Burnham Beeches Station (G.W.R.). Cards may be handed in till 8.30 p.m.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	0 4 0
Each additional line	0 0 6
A whole column	2 13 4
A page	8 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance, not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication: and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at Postes Restantes addressed either in initials or numbers.

The Croonian Lectures

ON

RADIO-ACTIVITY AND CARCINOMA.

AN EXPERIMENTAL INQUIRY.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF LONDON IN JUNE, 1909.

By W. S. LAZARUS-BARLOW, M.D., F.R.C.P.,

DIRECTOR OF THE CANCER RESEARCH LABORATORIES, THE MIDDLESEX HOSPITAL.

[WITH SPECIAL PLATE.]

LECTURE I.

After thanking the College for the honour it had done him in inviting him to deliver the lectures, pointing out that the inquiry was still incomplete and that contributions to the entire research had been made by numerous workers in the Cancer Research Laboratories of the Middlesex Hospital, the lecturer proceeded as follows:—

The leading idea throughout the whole research has been the undoubted fact that workers with x rays are liable to suffer from carcinoma of the hand. It is unnecessary to labour this point in view of the conclusive evidence furnished by my former assistant, Mr. C. W. Rowntree, in this Hunterian Lecture before the Royal College of Surgeons of England on March 17th, 1909. From a careful examination of the microscopical sections shown by Mr. Rowntree, I am convinced that he is right in describing the x -ray condition which may follow on a somewhat severe and prolonged dermatitis occasioned by exposure to x rays as a squamous cell carcinoma.

Into the question of the relationship of the x rays to the carcinoma, whether it is specific and direct or non-specific and, so to speak, accidental, I do not propose to enter here. It will be more convenient to deal with the whole subject at the conclusion of the lectures. For the moment it will suffice to allow that exposure to x rays and carcinoma of the hand are closely related in certain cases.

The next idea of importance in connexion with the research is that for many years certain physical agents have been considered by the profession to be causally related to cancer of special sites. Thus clay pipes have been associated with cancer of the lip, paraffin and tar with cancer of the hands and arms of workers with these substances, soot with cancer of the scrotum in chimney sweeps, gall stones with cancer generally and particularly with cancer of the gall bladder. In addition, betel-nut chewing has been associated with cancer of the cheek, especially in Ceylon and the East, where the habit is common; use of the kangri has been associated with "kangri cancer" in Kashmir, while bilharziosis in Egypt has been held accountable for cancer of the bladder. Similarly it has been noted that cancer occasionally develops on old scars, on the floor of chronic ulcers, and on the site of lupus.

An approximation of these two ideas suggested the inquiry whether the clay pipes, the paraffin, tar, soot, etc., emit x rays or give other evidence of radio-active properties. If the answer to this question were in the positive, a single factor would be demonstrated to be present in a group of physical agents differing to the widest degree from one another, and the probability that each particular variety of cancer depended upon the physical agent usually inculcated would be strengthened, while presumption would be raised for the proposition that the common factor in all the physical agents—that is, their radio-activity—is causally related to the common factor in the pathological conditions to which they all are supposed to give rise—that is, the cancer.

It is remarkable that the cancer in all the cases that have been mentioned above, with the sole exception of that affecting the gall bladder, is squamous cell carcinoma. Moreover, the histological diagnosis is almost invariably to be made with great ease, Malpighian cells, prickly cells, and epithelial pearls being conspicuous. For this reason the present research has been confined to the group of carcinomata, meaning thereby squamous cell, columnar cell, and spheroidal cell carcinomata as determined by microscopical examination.

The research, therefore, resolved itself into a determination whether clay pipes, etc., and carcinomatous material give evidence of radio-activity.

The two chief criteria of radio-activity relied on by the physicist are (1) the action of the substance in question upon a charged electroscope and (2) its action upon a photographic plate in the dark. Of these criteria action upon a photographic plate in the dark is well known to the medical profession in the production of skiagraphs, but it is upon the electrical properties that the physicist places more reliance.

Owing to the fact that the x -ray tube only emits gamma radiations, while such radio-active substances as radium, uranium, and thorium emit alpha particles, beta rays, and gamma rays, while they also are far more complex than their chemical names would suggest, it became necessary to consider these substances as well as the x rays. It is clear that a substance may belong to the radio-active group and yet fail to produce gamma radiations. Thus, "chemically pure" uranium oxide emits alpha particles and beta and gamma rays, but the physicist can separate a uranium oxide from this, which is indistinguishable in its chemical reactions, but differs electrically in emitting alpha particles alone. Such uranium is without effect upon a photographic plate, though it affects a charged electroscope.

In addition to their power of affecting a photographic plate in the dark, radio-active substances emitting gamma rays with their high velocity and penetrating power, or beta rays with their somewhat lower but still great velocity and penetrating power, have the property of affecting the photographic plate though separated from the film by such substances as aluminium, mica, etc. This property forms an important means of differentiating the action of a recognized radio-active substance, such as radium or thorium, from other substances which apparently fail to possess the power of acting through a screen. How far this differentiation between radio-active and non-radio active substances may be carried by this method will be discussed later.

Electrically, the recognized radio-active substances have the property of accelerating the discharge of an electroscope whatever the sign of the electricity with which its leaves are charged. This property depends upon the fact that the radio-active substance by the alpha particles (helium atoms charged +), beta rays (negative electrons) and gamma rays which it emits, ionizes the air in the electroscope, breaking the molecules up into their constituent atoms, each of which is electrically charged + or -. These charged atoms collide with the charged gold leaves, and such as are of opposite sign to the charge on the leaves neutralize a corresponding amount of electricity on the leaves. The greater the ionization of the air in a given time the more rapidly the charged leaves fall together, and the greater the radio-activity of the substance under investigation is said to be.

From what has been said it follows that the various substances dealt with in the present investigation call for consideration (1) as regards their action when exposed to a photographic plate in the dark, and (2) as regards their influence upon the rate of leak of an electroscope (a) charged + and (b) charged -. In addition, it is necessary to determine the same points in regard to non-carcinomatous substances, and, further, to determine the influence of radio-activity upon the division of cells by direct experiment.

In the present lecture I propose to show that certain animal tissues and other substances have the power of acting upon a photographic plate in the dark. In the second lecture I shall consider, as far as possible, the properties and nature of the substances in the tissues which possess this power. The third lecture will be devoted to a consideration of the electrical properties of the carcinomatous and non-carcinomatous substances; while the fourth lecture will deal with the influence of radio-activity upon cell division, and will include a short general survey of the bearings of the experiments.

THE SKOTOPHOTOGRAPHIC ACTION OF CERTAIN ANIMAL TISSUES AND OTHER SUBSTANCES.

If a sample of human liver be minced, dried in the hot-air oven at 100–110° C., reduced to a powder and some of

* I have ventured to use the word "skotograph" to signify the effect that is produced upon a photographic plate by certain substances in the dark (error, darkness), on the analogy of "photograph," "radio-graph," and "skiagraph." The effects to which attention is about to be directed are certainly not photographs in the ordinary sense of the word, neither are they skiagraphs, while to term them radiography would be to assume the point at issue.

this powder be placed on a photographic film in the dark and the plate and powder be kept in contact in complete darkness for a certain length of time, it will probably be found, on developing the plate, that the former situation of the powder is indicated by a more or less considerable, punctate, deposition of silver. Prior to development the photographic plate shows no alteration. Similarly, if a "pure" cholesterol gall stone be exposed to a photographic plate in the dark, subsequent development of the plate will probably show an intense deposition of silver which occupies a larger area than corresponds to the area of the calculus in contact with the plate (Figs. 1 and 2). Skotographic action is not manifested by all animal substances, for example, it is rarely produced by spleen or lung dried and powdered as above, while numerous experiments made with uric acid calculi, paraffin wax, and clay pipes have shown that these substances possess no skotographic power. Similarly certain varieties of micro-organisms possess marked skotographic power, while others appear to be totally deficient.

It is unnecessary here to enter into the details of the method for obtaining skotographs, or the precautions to be taken in order to eliminate the action of light or of any outside influence of a recognized radio-active nature. These are all given elsewhere.¹ It must be stated, however, that the values assigned to the various plates showing skotographic action were determined by comparing them with the effect produced in a photographic plate by allowing x rays to act upon it through a Benoit's gauge. Since the gauge consists of aluminium graduated in thickness from 1 mm. to 12 mm. a graduated deposition of silver takes place on the plate. It was possible to graduate the degrees of silver deposition by this means from 0 to 6; and since the same skiagraph was used throughout, the values given for the various substances and tissues are comparable among themselves.

Tissues from Non-malignant Cases.

In all, tissues from 115 bodies of persons dying from some cause other than malignant disease were examined skotographically. In most instances the examination included samples of liver, kidney, spleen, and lung. The patients were of both sexes and of all ages; they were grouped for purposes of comparison into the following age-periods:

Under 2 years of age.	35 to 45 years.
2 to 20 years.	45 to 55 years; and
20 to 35 years.	Over 55 years of age.

This grouping of age-periods was made in order to institute a comparison with similar tissues derived from cases of carcinoma. In addition to the above, specimens of brain, pancreas, breast, liver of sheep and of ox, tissues of mouse, guinea-pig, and rabbit were examined skotographically, but no reference to the results will be made here.

The results of the investigation are summarized in the following table:

Table showing Mean Skotographic Values of Liver, Kidney, Spleen, and Lung in 115 Non-malignant Cases.

Age.	Males.				Females.			
	Liver.	Kidney.	Spleen.	Lung.	Liver.	Kidney.	Spleen.	Lung.
Under 2 years (10 males, 40 females)	1.7	2.3	0.8	0.9	3.1	1.6	0.7	1.1
2 to 20 years (9 males, 6 females)	2.1	2.4	0.6	0.4	3.2	2.8	0.4	0.6
21 to 35 years (12 males, 10 females)	3.0	2.6	1.1	0.75	3.7	2.3	0.5	0.6
35 to 45 years (9 males, 10 females)	2.7	1.6	0.3	0.0	13.4	3.9	0.9	0.5
45 to 55 years (10 males, 10 females)	3.3	1.4	0.5	0.0	4.2	2.7	0.8	0.8
Over 55 years (11 males, 8 females)	3.9	2.0	0.5	0.9	2.6	2.5	1.1	0.29
Means at all ages (61 males, 54 females)	2.8	2.1	0.6	0.6	3.4	2.8	0.8	0.6

From this table it appears that liver and kidney possess a far higher skotographic power than spleen or lung, and that the female tissue in each case had a greater skotographic power than the corresponding male tissue.

Owing to the large size of the liver and to the fact that it exerts the largest amount of skotographic effect, the figures for it may be examined more closely. It is seen

that the skotographic power of the liver in males increases steadily throughout life, with the exception of a fall at the age-period 35 to 45 years. In females this rise in skotographic power of the liver, including the fall at the age-period 35 to 45, is also seen. But whereas the values for the male reach their highest in the age-period "over 55 years," this same age-period in females witnesses a remarkable fall in skotographic power of the liver. Further reference to this point will be made in the last lecture.

The small mean values obtained for the spleen and lung are due to the fact that occasionally these organs exert a definite effect. Two-thirds of the total number of spleens examined skotographically, and two-thirds of the total number of livers, were absolutely without skotographic power. On the other hand, only one-fifth of the total number of livers examined skotographically were without effect.

Carcinomatous Material.

The skotographic value of the primary mass has been determined in 17 cases of carcinoma; of secondary growths, 29 specimens from 24 cases have been examined; 11 of the cases were male, 30 female. Two primary and four secondary growths were without skotographic effect, or the effect was doubtful. The mean skotographic value of the male primary masses was 2.0, male secondary masses 2.5; that of the female primary masses was 3.6, female secondary masses 3.2. Hence the superiority of the skotographic value of female tissue over that of male tissue obtains also in the case of carcinoma (Figs. 3 and 4).

Tissues from Cases of Carcinoma.

The skotographic values of the liver, lung, kidney, and spleen have been determined in 72 cases of carcinoma, 41 of which showed important metastases, and 31 insignificant metastases or none at all. The cardinal facts that liver and kidney exert a greater skotographic power than lung and spleen, and that the skotographic power of a female tissue is greater than that of the corresponding male tissue, are shown in this class of case as in that in which there is no malignant disease. But it appears that the carcinomatous condition is not without effect upon the skotographic power of the various tissues. This is best seen by considering the case of the liver. The effect of carcinoma upon the skotographic power of the liver may be considered in two ways:

1. Livers, themselves free from metastasis, may be compared skotographically according as they are derived from cases in which the total mass of carcinomatous material in the body is great or is small.

2. A comparison may be made between the hepatic tissue of non-malignant cases and the hepatic tissue of carcinomatous cases in which the liver is the seat of numerous large metastases.

These two different methods of approaching the question agree in indicating that carcinoma augments the skotographic power of the liver in males and decreases it in females. In the following table are given the figures upon which this statement is founded.

Table to show the Influence of Carcinoma on the Skotographic Power of the Liver.

Age.	Males.				Females.			
	No. of Cases.	Mean Growth in Liver.	Mean Growth in Body.	Little Growth in Body.	No. of Cases.	Mean Growth in Liver.	Mean Growth in Body.	Little Growth in Body.
Under 35	3	—	—	—	3	2.0	1.7	1.0
35-45	2	3.6	2.75	—	3.4	3.5	3.7	4.25
45-55	3	3.6	3.5	1.8	4.2	—	3.7	4.0
Over 55	4	4.5	4.5	3.8	2.6	2.5	2.5	2.6

But consideration of the above table shows that the matter is not so simple. For, although male hepatic substance in the neighbourhood of liver metastases is more skotographic than non-malignant liver while the converse is true in the case of the female, and although male

hepatic substance where there is much growth in the body is more skotographic than when there is little while the converse is true in the case of the female, a small amount of carcinoma in the body appears to diminish the skotographic power of the male liver, while it augments that of the female liver. I do not attempt an explanation of these points; indeed, they need confirmation on a much larger number of cases. The regularity with which female liver and male liver act in opposite directions, in the face of what is apparently a single condition—that is, carcinoma—is, however, such that it suggests the existence of some sort of interaction between carcinoma and the skotographic property of the liver. On the other hand, we may be quite wrong in considering carcinoma as a single condition relative to the two sexes; it has already been shown that male and female carcinomatous materials differ in skotographic power.

The only condition in which a thoroughly satisfactory determination can be made of the influence of carcinomatous growth upon the skotographic power of the tissue in which it lies is that in which one of paired organs is the seat of metastasis. This is relatively so uncommon, and when it occurs the chance that the metastasis will be sufficiently large to influence the neighbouring tissue of the organ to any extent is so small that I have only obtained a single example. The case was one of carcinoma of the cervix, and one kidney was the seat of a fairly large number of metastases, while the other was free. The renal substance of the unaffected kidney had a skotographic power of 3, while the renal substance of the affected kidney was absolutely without effect upon the photographic plate. This case, therefore, conformed to the statement made above for the liver that, in the female, carcinoma leads to a diminution of the skotographic power of the tissue in which it lies.

"Substances commonly supposed to be causally related to Carcinoma.

Numerous samples of clay pipe, soot, pitch, paraffin wax, metallic arsenic, arsenious oxide, betel nut, cholesterol gall stones, pigment gall stones, renal and vesical calculi, have been examined skotographically, the calculi, renal, biliary, and vesical, being made the subject of an extended research by Dr. Colwell.³ Skotographic effect was exhibited by one sample of soot out of two examined, by betel nut on all of numerous occasions, by each of twenty-three specimens of cholesterol gall stone, more or less "pure," in three out of four samples of pigment gall stones examined, the effect being always very slight as compared with the action of the cholesterol calculi, and by thirty out of thirty-eight vesical calculi. Metallic arsenic and arsenious oxide produced effects upon the photographic plates, but inasmuch as the films showed alteration before development the action cannot be regarded as skotographic. On the other hand, none of nine specimens of clay pipe, of numerous samples of paraffin wax, of four samples of pitch from different localities, of several specimens of coal, yielded the slightest trace of skotographic action.

In the case of cholesterol gall stones the action on the plate extends widely beyond the area of the surface of the calculus in contact with the plate, but in the case of all the other substances the area of silver deposition was coextensive with the area of contact between substance and film. This is well seen in the skotographs of vesical calculi, in which rings of silver deposition alternate with rings of no deposition in such a way that a picture is formed of the surface of the calculus by which the skotograph was produced (Fig. 5). When the nucleus of a calculus, or certain laminae, or the entire calculus consists of "pure uric acid," the corresponding part of the film shows a complete absence of skotographic effect. As a rule, calculi or laminae in calculi consisting of ammonium urate, calcium oxalate, calcium phosphate, or ammonio-magnesium phosphate possessed skotographic power; but since instances to the contrary were found Dr. Colwell concluded that the chemical substances in question, *as such*, were not the effective agent. Similarly he found that purified cholesterol obtained from a gall stone which produced a profound effect upon a photographic plate was itself entirely devoid of skotographic power.

Skotographs of betel nut are of especial interest in connexion with the observation made by Dr. Russell, F.R.S.,⁴ that almost all varieties of wood affect a photo-

graphic plate when placed in contact with it under conditions of total darkness—that is, possess skotographic powers. This power is possessed by the winter and spring woods in different degrees, so that a skotograph of a piece of wood reproduces a picture of the grain of the wood in the same way as a skotograph of a vesical calculus reproduces the appearance of the cut surface of the calculus. Similarly a skotograph of a bisected betel nut shows the peculiar markings of the nut in all their detail (Fig. 6).

LECTURE II.

THE NATURE OF SKOTOGRAPHIC ACTION.

RUSSELL'S researches upon the effect of various woods upon a photographic plate in the dark led him to the conclusion that the deposition of silver is occasioned by traces of hydrogen peroxide formed owing to oxidation of the terpenes and other resinous substances in the wood in the presence of moisture. This strictly chemical action, albeit produced by traces of hydrogen peroxide so minute as to be beyond detection by any other method, is distinguishable from the action brought about by ethereal vibrations, such as those of beta or gamma rays, by the fact that it is completely inhibited by interposing a thin screen of mica between the wood and the film. Russell showed, further, that wood which had been exposed to strong sunlight before being placed in contact with the photographic film produces a far stronger effect than wood which has been kept in the dark.

Under these circumstances it became necessary to determine as far as possible with what constituent or constituents of the animal tissues their skotographic power was bound up, and subsequently whether that power conformed more to the type of a chemical substance, and particularly to hydrogen peroxide, or more to that exerted by ethereal vibrations.

It must be stated at the outset that a complete answer cannot be given to the above questions. It can rather be said what the skotographic power is *not* bound up with than what it *is*. Similarly it will be found that it is impossible to include it definitely in the chemical or the physical group of phenomena, since in certain respects it appears to resemble hydrogen peroxide and in others to resemble an ethereal vibration.

Attempts at Isolation of the Skotographic Substance.

The skotographic substance, or substances—for there is reason to believe that, in the liver at least, two substances exist which differ from one another in certain reactions but agree in affecting a photographic plate in the dark—is not protein, or fat, or carbohydrate, or colouring matter or mineral salts. Each of these constituents of the tissues has been definitely excluded. It is unnecessary to enter into a detailed account of the method in which this has been done, for it has been recorded elsewhere.⁴ The following short account will suffice.

That it is not *protein* is indicated by the fact that it is yielded by liver, for example, and not by spleen, while the same fact shows that it is not dependent upon the "cellularity" of the tissue as such. But the non-protein character can be shown by obtaining a completely protein-free extract of the tissue, and proving that this extract still possesses skotographic power. Fig. 7 shows that this is the case. It was produced in the following way: Liver of sheep was minced and allowed to stand under distilled water for eighteen hours. The watery extract was then acidified, boiled, and filtered. To the filtrate three times the volume of basic lead acetate in solution and suspension was added, and the resulting precipitate was filtered off. Then sulphuretted hydrogen was passed through the filtrate to precipitate the lead, and after the filtrate from this operation had been concentrated to small bulk upon a water bath it was added to twenty times its volume of absolute alcohol and allowed to stand for three weeks. The merest trace of precipitate was formed, and was filtered off, and the alcohol was removed by evaporation. The residual fluid was then used to write certain words on a plain glass plate with a camel-hair pencil, and this plate was exposed to the photographic film under skotographic conditions and separated from contact with the film by strands of cotton. It is seen that this watery extract of liver, in which none of the laboratory tests for protein shows the slightest trace of that material, possesses intense skotographic power. The process for

purification from protein has been checked at every stage, as well as the reagents used, and it is certain: (1) That the skotographic power is not introduced during the process, and (2) that the various precipitates formed are devoid of skotographic power, except in so far as they are contaminated with the corresponding filtrate.

That the skotographic substance is not *fat* as such is shown by the fact that a material which has been rigidly extracted with ether still possesses skotographic power. Thus, all the powdered tissues that were used to arrive at the conclusions given in the first lecture were extracted with pure ether in a Soxhlet apparatus for a minimum of six hours before being examined skotographically. This method extracts the phosphorized as well as the non-phosphorized fats.

Just as the watery extract of a liver, for example, possesses skotographic powers so it is possessed by an ethereal extract. Into the question of the actual constituent of the ethereal extract which possesses the power it is impossible for me to enter. The chemical analysis I have not attempted, owing to its difficulty.

That the skotographic substance is not *carbohydrate* as such is proved by the facts that some of the extracts by which it is manifested contain carbohydrate while others are devoid of it, that it is manifested by ethereal extracts, and, as will be shown later, that it survives charring.

The fact that the skotographic power is independent of the water-soluble and the ether-soluble pigments of the tissue is shown by the persistence of effect if one of these extracts be decolorized by finely divided animal charcoal.

And, finally, that it is independent of the *mineral constituents* of the tissue—at least those which survive a temperature of 300° C. (see below)—is shown by the fact that the ash of a tissue which possesses marked skotographic power is entirely without effect upon a photographic plate in the dark.

The skotographic power of any tissue is completely removed if it be first extracted with water and subsequently with ether. This appears from the accompanying figure (8), in which the upper fourth shows the effect of the original substance, the second fourth shows the effect of a watery extract, the third that of an ethereal extract made subsequently to the watery; the bottom fourth, over which there is an absence of skotographic action, was exposed to the solid residue after the watery and ethereal extractions. A similar absence of skotographic power characterizes a tissue which has been extracted with acetone, as might be expected, since it dehydrates and also extracts fat.

Just as the skotographic power is contained in the watery and ethereal extracts so it is contained in one made by acetone, and by evaporating with care the constituents of the original skotographic material which are soluble in water and those which are soluble only in strong acetone may be divided. They are apparently the same as those which are contained in the watery and ethereal extracts when these are made separately.

But though it is clear that the skotographic power is not a property of protein as such, there is no doubt that it is a property of certain organic substances, as distinguished from inorganic, that are probably derived from protein. As will be said later the skotographic power is not destroyed even though the substance manifesting it be heated to a temperature of 300° C. Such a temperature chars the substance, and no doubt breaks up much of

the protein, but from it a material, often of polymorphic crystalline character, but highly deliquescent, can be separated which exerts a skotographic effect, and which is still organic in nature, as shown by the fact that it chars on further heating. By repeated solutions in water and precipitation with absolute alcohol this crystalline material can be divided into a honeylike non-crystallizable and a colourless crystallizable portion. The skotographic power resides chiefly, if not entirely, in the honeylike, highly deliquescent material. This material is dialyzable with ease, and carries with it the actual skotographic substance. Further than this analysis has not gone.

CONDITIONS DETERMINING THE MANIFESTATION OF SKOTOGRAPHIC POWER.

It has been shown above that I have not succeeded in isolating the skotographic substance, though it has been stripped of certain materials with which it is usually associated. It has therefore been necessary to investigate the skotographic property upon crude material, and for this purpose the ether-extracted, dried, and powdered original material and watery extracts that have been freed from protein in the way already described, have chiefly been used.

Relation of Substance to the Photographic Film: Contact: Proximity: Screens.

All the photographic effects to which reference was made in the first lecture were obtained by allowing the powdered substances to lie in actual contact with the photographic film, but there is no doubt that they can act at a little distance. This is better seen in considering the watery extracts, for when they were under investigation contact with the film was necessarily excluded. Attempts were made to determine the maximum distance at which recognizable photographic effect is produced by exposing a glass plate bearing the watery extract to the photographic plate at an angle. In this way, and using photographic plates specially sensitized for x rays, it was found that the watery extract used for producing Fig. 7 is still effective when it is separated from the film by a distance of 15 mm.

DESCRIPTION OF PLATE.

Fig. 1.—Skotograph of dried, powdered, ether-extracted, non-malignant liver.

Fig. 2.—Skotograph of pure cholesterol gall stone. Action occurs well beyond the limits of the calculus.

Fig. 3.—Skotograph of dried, powdered, ether-extracted primary spheroidal cell carcinoma of breast.

Fig. 4.—Skotograph of dried, powdered, ether-extracted pulmonary metastasis from a case of spheroidal cell carcinoma of the breast.

Fig. 5.—Skotograph of a mixed phosphatic and uratic calculus.

Fig. 6.—Skotograph of a section of a betel nut. The dark crescent was at the seat of a film of celluloid two years old.

Fig. 7.—Skotograph produced by a protein-free watery extract of sheep's liver. Material prepared and skotograph taken March 24th, 1908. Compare with Fig. 10.

Fig. 8.—Skotograph showing that the power of affecting a photographic plate in the dark manifested by dried, powdered, non-malignant liver (top quarter) is entirely removed (bottom quarter) by extraction with water and subsequent extraction with ether. The extracts possess strong skotographic power.

Fig. 9.—Skotograph showing that the effective agent in cedar-wood oil can be transported in a current of air. The air impinged on the photographic plate at the apex of the triangle of silver deposition.

Fig. 10.—Skotograph taken with protein-free watery extract of sheep's liver used to produce Fig. 7 over a year after its original preparation.

Fig. 11.—Skotograph of a phosphatic calculus removed by Percival Pott (died 1788).

Fig. 12.—Skotographs on Ilford x-ray and on Imperial special rapid plates produced by the same sample of dried, powdered, ether-extracted carcinoma material under identical conditions. Compare with Fig. 13.

Fig. 13.—Skotograph on Ilford x-ray and on Imperial special rapid plates produced by the same sample of sawdust under identical conditions. Compare with Fig. 12.

Fig. 17.—Skotographs of dried, powdered, and ether-extracted testis and ovary of herring. The testis produces the greater deposition of silver. (This specimen will be referred to in Lecture IV.)

The question of screens between the material and the photographic film is one of fundamental importance in trying to arrive at a conclusion as to the nature of skotographic action, and must, therefore, be dealt with in some detail.

It may be stated at the outset that interposition of a screen of the order of thickness of that used in examining the effects of recognized radio-active materials such as uranium or thorium between the animal substance under investigation and the photographic film completely eliminates skotographic action. This is true whether the screen be metallic (for example, aluminium) or non-metallic (for example, mica), however intense the skotographic action may be in the absence of a screen, or however long (up to six weeks) the exposure may have been, and even though it had been carried out at 55° C.

On the other hand, the matter is not simple, as the following experiments show:

If a flat section of a betel nut or of liver be coated with a thin film of celluloid and the whole be exposed to a photographic plate in the ordinary way, it will be found that the greatest deposition of silver occurs on that part of the plate which was separated from the substance by the celluloid. That this effect is not due to the celluloid itself is shown by the fact that an old film of celluloid is entirely without skotographic effect, and in the betel nut experi-

ment the celloidin had been painted on the nut two years before it was exposed to the photographic plate (Fig. 6).

In the second place, if an albuminate of thorium be made by allowing a solution of the nitrate to fall into egg-white, the resulting precipitate after drying and powdering fails to affect a photographic plate through a film so thin as that produced by brushing a minute quantity of egg-white over tissue paper, though a fair deposition of silver occurs when the albuminate is separated from the photographic film by tissue paper uncoated with egg-white. Such an albuminate of thorium contains about 10 per cent. of the radio-active element by weight. Even in this case it is possible that such direct skotographic effect as was produced was due to uncombined radio-active salt, since the precipitate was not washed for fear of hydrolysis. In several instances, where the precipitate with thorium was washed thoroughly with hot water before drying, it failed to produce an effect upon the photographic plate even though it were actually in contact with it during exposure; nevertheless, such samples of albuminate showed the presence of considerable amounts of thorium on analysis.

Hence under special conditions a vegetable or animal tissue may produce skotographic action through a thin film of celloidin and a recognized radio-active substance may fail to affect a plate through a film of egg-white or probably even a greater tenuity.

Effect of Temperature.

Within the limits of -3°C . and 100°C . it may be said that the skotographic action of the tissues is independent of the temperature provided that the exposure be longer at the lower temperatures. Thus a degree of silver deposition which can be attained by exposing a cholesterol gall stone for eighteen hours at 55°C . to the photographic plate can only be obtained after an exposure lasting for weeks at the room temperature, and probably for several months in the ice chamber at -3°C . Exposure of the substance to a plate at a dry heat of 100°C . is an unsatisfactory procedure, but if the exposure be shortened to about half an hour, silver deposition is not general, but is confined to the part with which the substance under investigation was in contact. The general temperature at which the skotographs in this research were taken was 55°C ., and the length of exposure was eighteen hours. Except in certain cases, Imperial special rapid plates were used, and development was by 1 in 20 Rodinal.

I have dealt above with the temperatures at which the substance has been exposed to the photographic plate, but the substance itself may be exposed to a much higher temperature without undergoing complete loss of skotographic power. I have not been able to determine with exactness the highest temperature to which a skotographic substance may be raised without undergoing complete loss of its power; but it is certain that a skotographic watery extract painted in a thin layer upon a No. 1 coverslip and exposed to dry air at about 280°C . for five minutes will probably afford evidence of skotographic power, while a similar coverslip exposed to about 300°C . will not. In any case it is certain that the skotographic power is not destroyed by a temperature (about 200°C .) which chars the substance itself and therefore in large measure disintegrates it.

Light and Darkness.

Leaving on one side such points as the fact that the change in the photographic plate is not due to the hygroscopic character of the partially purified skotographic substance, the gradual disappearance of the power on continued exposure to air, the curious way in which occasionally there occurs a recrudescence of skotographic power in a watery or acetone extract, the fact that the power is independent of the acidity, basicity, or neutrality of a watery extract—points which have been made the subject of many experiments and are of great theoretical interest—I pass to certain experiments instituted in order to compare the skotographic power of animal tissues with that manifested by woods and held by Russell to depend upon the presence of hydrogen peroxide.

Russell found that the skotographic power of a wood is profoundly influenced according as it has been exposed to light, and especially direct sunlight, or has been kept in darkness before exposing it to the photographic plate. If exposed to light, the skotographic power is always intensified; if kept in darkness, it is always diminished. In the case of animal tissues and of calculi of different kinds

this point has been carefully investigated by myself and by Colwell respectively. We agree in finding that our substances do not show the slightest difference in skotographic power, even though they may be exposed to direct sunlight or be preserved in total darkness for a period of six months before placing them in contact with the photographic film.

Volatility.

Inasmuch as the skotographic power of an animal substance disappears after about a fortnight if it be exposed freely to air, it was thought that the effect might be due to some volatile product. Apart from the fact that it is difficult to imagine a volatile substance which can withstand a temperature of 300°C ., below which the skotographic power is not destroyed, the question has been approached directly. By causing a current of air which had passed over cedar-wood oil, or clove oil, or oil of cajuput, or oil of origanum, to impinge upon a photographic film, it was found that volatility, as such, is not the effective cause of a skotographic effect since a skotographic effect was produced in the case of air charged with the volatile products of oil of cedarwood alone. Further, it has never been found possible to carry over the skotographic power of any of the substances used in the present research although they frequently give off volatile products with powerful odours that can be detected in the stream of air impinging upon the photographic film by the sense of smell. Fig. 9 shows the skotographic effect of a current of air charged with the volatile products of cedarwood oil.

Is Skotographic Action essentially due to Hydrogen Peroxide?

The experiments made bearing on this question were of two kinds. In one set Colwell took a cholesterol gall stone, which yielded a profound skotographic effect, and prepared from it a sample of purified cholesterol. Examined skotographically, this purified cholesterol was absolutely without effect. He now exposed a thin film (made by dissolving cholesterol in chloroform, pouring it on a glass plate, and allowing the chloroform to evaporate) to an atmosphere fully charged with hydrogen peroxide vapour for twenty-four hours at a temperature of 53°C . Similarly he exposed to hydrogen peroxide vapour a vesical calculus normally possessing no skotographic power. He found that now both cholesterol and vesical calculus affected the plate profoundly, but that within twenty-three hours of their removal from the atmosphere of hydrogen peroxide they had completely regained their original freedom from skotographic power. Probably the last traces of hydrogen peroxide had disappeared long before twenty-three hours, but of this there is no proof. This experiment bears upon the length of time during which skotographic power is held by a substance—a subject which will claim our attention shortly.

The second set of experiments concerns the so-called peroxydase effect shown by certain tissues. In its best-known form the peroxydase reaction is represented by the guaiacum test for blood. It depends upon an oxidation of the traces of guaiaconic acid present in the freshly-prepared tincture of guaiacum by oxygen that has been set free from hydrogen peroxide by a substance (peroxydase) present in the substance undergoing the test.

In examining a large number of dried and powdered tissues from this point of view, as well as from that of their skotographic power, I found, speaking generally, that the degree of peroxydase reaction manifested by them and measured against a standard graduated series of blue solutions, varies inversely with the skotographic power.

Table showing Results in Two Series of Ten Consecutive Specimens.

No.	Tissue.	Photo-graphic Value.	Peroxy-dase Value.	No.	Tissue.	Photo-graphic Value.	Peroxy-dase Value.
220	Kidney	6	0	320	Liver	6	2
221	Lung	4	6+	321	Kidney	3	4
222	Liver	3	5	322	Liver	5	3
223	Kidney	4	0	323	Kidney	3	5
224	Lung	2	4	324	Liver	5	0
225	Spleen	3	6+	325	Kidney	2	6
226	Liver	4	0	326	Liver	4	1
227	Kidney	2	0	327	Kidney	2	4
228	Spleen	2	4	328	Liver	3	5
229	Lung	0	2	329	Kidney	2	5

This fact would seem to indicate that a tissue possessing a large amount of a substance which splits up hydrogen peroxide has but little skotographic power, and conversely that a substance exerting a great skotographic power contains but little of the hydrogen peroxide splitting property. From this it is but a step to the conclusion (with Russell) that the skotographic property is in reality nothing more than a manifestation of the action of hydrogen peroxide upon a photographic plate.

But that this conclusion is not justified is shown by two sets of observations.

First, I have found that skotographic effect may be shown by watery extracts which from beginning to end of their exposure to the photographic plate contain peroxidase and are therefore in a condition to split up any hydrogen peroxide that may be formed immediately on its production. And secondly, the inverse relations of peroxidase and skotographic power do not obtain for dried and powdered carcinomatous material, for such material, whether it produce a great skotographic effect, or a slight one or no effect at all, is devoid of peroxidase. Amongst seventeen samples of dried and powdered carcinomatous material examined for the purpose only four contradictions were found. One of these is explicable by the fact that the growth was a pulmonary metastasis, and probably contained some pulmonary tissue which has, normally, a high peroxidase coefficient, and the remaining three, all of which were hepatic metastases, gave the least recognizable amount of peroxidase.

Duration of Skotographic Power.

Strictly speaking, the length of time during which a substance retains skotographic power can only be determined in the case of such materials as have actually been prepared. Thus, the material used in the production of Fig. 7 was prepared on March 24th, 1908, and inasmuch as a skotograph taken with the same substance a year later (Fig. 10) also shows effect, it is clear that the substance in question retained the power for that length of time. Numerous skotographs taken at intermediate times showed that the power was present throughout.

From the time of its preparation the substance was kept in a clear stoppered bottle in the laboratory without any special precautions. This experiment renders it probable that a substance which at any time shows skotographic power also possessed it at the time of its original formation, and this assumption becomes of importance in connexion with the skotographic power of calculi. Colwell has shown that cholesterolin calculi will often produce intense skotographic action directly after their removal from the body, but he has also shown that intense skotographic power may be shown by a cholesterolin gall stone that had been preserved in the museum of the hospital for over twenty-five years. In the case of vesical calculi he goes much further; for a calculus removed by Percival Pott, who died in 1786, shows well-marked skotographic power (Fig. 11), and faint but definite skotographic power is shown by a calculus removed from the body of a pre-dynastic Egyptian mummy, and therefore at least 7,000 years old.

Use of Photographic Plates Specially Sensitized for X-ray Work.

Recently plates have been put upon the market which are specially sensitized for x-ray work. It was thought that a series of comparative tests of the same substances, when exposed to these and to ordinary plates, might indicate whether the skotographic power of the substance under examination was more akin to light or to x-rays. Dried, powdered, and ether-extracted carcinomatous material from a metastasis in the liver and ordinary deal sawdust were examined in this way. It was found that the first appearance of action on the x-ray plate occurred at the end of the sixth hour of exposure, and on the Imperial special rapid plate not till the end of the seventh hour (the powdered growth being separated from the photographic films by thin layers of filter paper), and that the ultimate density of silver deposition was

greater also on the x-ray plate. When the material was not separated from the photographic film by filter paper, the first appearance of action was observable on both plates at the end of the first hour of exposure; but whereas it was quite marked on the x-ray plate, it was only just distinguishable on the other. In the case of sawdust these differences did not show themselves, the deposition of silver on the ordinary plate being very nearly, though not quite, as intense as that on the x-ray plate (Figs. 12 and 13).

Skotographic Action of Bacteria.

MacCormac¹ has published the results of an investigation into the question whether skotographic action is exerted by bacteria. He examined in this respect 27 different varieties of micro-organism, and from his table they may be grouped as below:

GROUP I. NO SKOTOGRAPHIC ACTION.

B. Rabinowitch, *B. Cohn* I, *B. Gärtner*, *B. phosphor. albiensis*, *B. intestinalis sporogenes*, *B. Danyasz*, *B. mycoides*, *B. coli*, *V. cholerae*.

GROUP II. SKOTOGRAPHIC ACTION FICKLE.

Sarc. flava, *B. Flezner*, *V. Metchnikovi*, *B. Hoffmann*, *B. megaterium*, *M. citreus agilis*, *B. pyocyaneus*, *B. phlei* II, *B. prodigiosus*, *B. typhosus*.

GROUP III. SKOTOGRAPHIC ACTION USUAL AND CONSIDERABLE.

Staph. pyogenes aureus, *Staph. pyogenes albus*, *B. tuberculosis*, *B. tuberculosis bovinus*, *B. diphtheriae*, "pathogenic throat yeast."

The importance of these researches will be indicated later.

SUMMARY.

In this and the preceding lecture I have shown that certain of the tissues of the human body show skotographic action (liver, kidney), while certain do not (spleen, lung); that a larger amount of this property resides in female tissues that possess it than in male of the same kind; that the amount present in the liver increases from infancy to the age of 55 years, with an unexplained drop in both sexes during the age-period 35-45, and that after 55, while it increases still further in the case of males, in females it undergoes a sharp diminution. I have shown that carcinomatous material possesses skotographic power, whether it be primary or secondary, and that female carcinomatous tissue has a higher skotographic value than male; and that the existence of a mass of carcinoma in a tissue modifies its normal skotographic value. I have found that certain substances commonly supposed to be causally related to carcinoma possess the skotographic power to a high degree (cholesterin gall stone), while others are devoid of it (clay pipe, paraffin). I have endeavoured to throw some light upon the nature of the skotographic action manifested by animal tissues and certain other substances, comparing their behaviour with that of woods in which the action has been regarded as dependent upon the formation of hydrogen peroxide, and with that of recognized radio-active substances. On this point I have adduced evidence showing that the animal tissues and other substances under examination cannot, so far as their action upon a photographic plate in the dark is concerned, be grouped conclusively with the recognized radio-active substances or segregated into a class such as that formed by the woods, and believed by Russell to affect a photographic plate in the dark by means of a purely chemical action. They occupy an intermediate position and have affinities with the woods on the one hand, and with the recognized radio-active substances on the other. Lastly, MacCormac, working in my laboratory, has shown that bacteria may be divided into groups according to their skotographic power, and that the only group which acts in this way with constancy and to a marked degree is a small one, which includes the pyogenic staphylococci and the bacilli of tuberculosis and diphtheria.

The bearing of these observations upon the question of carcinoma must be left for consideration in the last lecture.

¹This calculus is preserved in the Museum of the Royal College of Surgeons, and was kindly lent by Mr. Shattock. Owing to its unique character, it was impossible to deal with it as with other specimens. Hence a flat surface could not be placed in contact with the photographic film. The original skotograph was shown during the lecture, but the markings, though definite, are too faint for reproduction in a plate without retouching, which is, of course, inadmissible.

A Lecture

ON THE

RED DEGENERATION OF UTERINE FIBROIDS COMPLICATING PREGNANCY.

DELIVERED AT THE MEDICAL GRADUATES' COLLEGE AND
POLYCLINIC, MAY 5TH, 1909.BY JOHN BLAND-SUTTON, F.R.C.S. ENG.,
SURGEON TO THE MIDDLESEX HOSPITAL, ETC.

Of all the genera of tumours to which women are liable, the uterine fibroid is the most common, and there is no genus of tumours which has such a definite age-distribution. Though the uterine fibroid is such a common tumour, like pregnancy, it only arises during the menstrual period of life, which in Great Britain covers an average period of thirty years, from the fifteenth to the forty-fifth. There is, however, this difference—from the twentieth to the thirtieth year pregnancy is extremely common, the occurrence of a large fibroid uncommon. From the thirtieth to the forty-fifth year women are as liable to grow uterine fibroids as to become pregnant. The interval between the twenty-fifth year and thirty-fifth year of a woman's life may be regarded as the great child-bearing period (Matthews Duncan). It is clear that in the interval between the thirtieth and fortieth years of life there is so much overlapping of the child-bearing period and the fibroid-growing period that the co-existence of pregnancy and one or more fibroids in the uterus ought to be fairly frequent; such is indeed the case (see table). In relation to the frequency of this combination, which, as I shall endeavour to show, is a piece of ill luck for any woman, we have to remember that uterine fibroids are quite as common in spinsters as in married women, and it is a fact that among barren married women fibroids are very common; and although those who practise midwifery cannot come to an agreement as to whether fibroids cause sterility, or sterility causes fibroids, women with fibroids often conceive. Pregnancy under such conditions often goes successfully to term; frequently it is a serious matter for the patient, especially if she be a primigravida who has married late in life and possesses a large fibroid in the lower segment of her uterus, or in its neck.

In this lecture it is my intention to deal with the influence which pregnancy exerts on the fibroids. The baneful effects which fibroids exercise on the fetus, especially those connected with delivery, are for the greater part mechanical, and will not be considered. The dangers to the mother constitute my theme on this occasion.

In order to realize the disturbance which pregnancy induces in uterine fibroids, we should remember that in a normal adult virgin the uterus is on an average 3 in. long, its wall is 1 in. in thickness, and the uterine cavity measures from the "os" to the fundus 2½ in., and the whole organ weighs between 2 and 3 oz. The pregnant uterus at term is about 13 in. long, with walls ½ in. thick; it weighs between 2 and 3 lb.; its capacity varies from 1 to 1½ gallons. At the full period of pregnancy it forms an ovoid muscular bag, the os uteri occupying the narrow end. These weights and measurements afford some notion of the extraordinary changes produced on the uterus by pregnancy.

The uterus differs from all other hollow viscera in the extreme thickness and rigidity of its walls. From the histologist's point of view it would appear to be the last organ in the body whose tissues would yield to an expanding force within, and gynaecologists sometimes appreciate this when they attempt to forcibly dilate it with hard metal instruments.

There are few physiological events so clearly appreciated as the simple, easy, and rapid way in which the uterine walls soften, stretch, and increase in size under the mysterious influence of an embryo growing within it. The changes may be expressed as increased vascularity, multiplication of the muscle cells, and softening of the uterine tissues.

When the walls of the uterus are occupied with fibroids and pregnancy ensues, it is undeniable that these tumours, depending as they do on the circulation of the uterus for nutrition, are often influenced by the altered conditions.

The changes wrought in them by pregnancy have been described by many writers as consisting in the softening and flattening out of interstitial fibroids; also that the tissues of these tumours multiply with the growth of the uterus coincident with pregnancy. Indeed, this supposed active growth of fibroids during pregnancy appeared to receive support by the fact, noted by many writers, that the tissues of fibroids lodged in a pregnant uterus often became red or flesh-coloured; this alteration in colour was supposed to be due to an increase in the muscular tissue of the tumour. Some observers attributed the alteration in colour to increased vascularity of the tumour, and others to actual bleeding into its tissue, and it seems somewhat odd that no one endeavoured to determine the nature of this striking change with the assistance of a microscope. Several surgeons, myself among them, had given some attention to this alteration in the colour and texture of fibroids in the walls of pregnant uteri, and realized they were degenerative changes. I had even taken the trouble to have several examples examined bacteriologically, but with negative results. In 1903 Fairbairn made a valuable communication to the Obstetrical Society, London, entitled "A Contribution to the Study of one of the Varieties of Necrotic Change—the so-called Necrobiosis in Fibro-myomata of the Uterus," which served to focus attention on this subject, and, among other matters, points out that he had failed to find micro-organisms in these red fibroids, and that the red degeneration occurred in fibroids lodged in the unimpregnated as well as in the gravid uterus.

It may be stated at once that the occurrence of red degeneration of fibroids in non-gravid uteri is admitted by all gynaecologists, but it is equally true that the change is more frequent, more extensive, and more intensive when associated with pregnancy.

Another important feature accompanying the red degeneration of fibroids when associated with pregnancy is pain and tenderness. I appreciated this in the first examples of the condition which came under my notice, and have persistently called attention to its clinical significance. Before considering this symptom in detail, it will be useful to describe the alteration wrought in the fibroids when the subject of this change.

The ordinary colour of the common hard uterine fibroid on section is dirty white, or very pale yellow; in many degenerating and necrotic fibroids the yellow deepens. During pregnancy a fibroid may assume a deep red or a mahogany tint. In the early stages a tumour undergoing this change exhibits the colour in streaks, but as the pregnancy advances the whole tumour becomes affected, and in well-marked examples the whole fibroid softens and becomes diffident. I have known such a softened tumour to rupture its capsule during the puerperium, and the red softened tissue to be discharged from the uterus in shreds (No. 2 in table); the medical attendant regarded this stuff as "retained secundines." In this instance the tissue was the colour of mahogany. Even in this fibroid no micro-organisms were detected in the bacteriological laboratory. This happened in 1901. The failure to find micro-organisms in these degenerating fibroids astonished me, especially as many of them immediately after removal exhale, on section, the peculiar odour of stale or putrid fish. On microscopic examination, the tissue of the fibroid is found to be necrotic, and refuses to stain; the characteristic redness is due to the diffusion of blood pigment through the necrosed tissues.

This softening of the tissue composing a uterine fibroid sometimes takes place with great rapidity, and reduces even the hardest (uncalcified) fibroid to the consistency of soft soap. Recently some new investigations on the nature and cause of this red degeneration have been published by Professor Lorrain Smith and Dr. Fletcher Shaw. They investigated with especial care four examples, of which three were associated with pregnancy, and in which the "outstanding clinical features were pain and rapid enlargement of the tumours." In two of the cases there were also symptoms of toxæmia. A study of the clinical history of the three pregnant women shows that it was chiefly on account of pain that they sought surgical assistance, and in each instance hysterectomy was performed with success. In the non-gravid patient hysterectomy became necessary mainly on account of menorrhagia, but in addition she complained of some interference

with micturition. The chief interest in Smith's and Shaw's communication lies in the opinions they express on the pathology of the change, and in the fact that they isolated from two of the specimens micro-organisms. In one they found staphylococci in the blood vessels and in another diplococci in the spaces round the vessels. These observers also express the opinion that "the chief change found in red degeneration of fibroids consists in thrombosis of the blood vessels." They also state their belief that tumours which have undergone this change "are liable to become infected by septic organisms, and so give rise to acute toxic symptoms."

I was deeply interested in reading an abstract of this paper, and within a few days the following remarkable case came under my notice:

A primigravida, aged 31, two months pregnant, was suddenly seized with such acute abdominal pain during a railway journey, that she left the train at an intermediate station, and placed herself under the care of a doctor whom she knew. He considered the patient to be suffering from the bursting of a gravid Fallopian tube, and sent for me.

I saw her twenty-four hours after the onset of the symptoms, and found a large tumour, probably a fibroid, occupying the right half of the belly and reaching as high as the liver. I considered that some change had taken place in this tumour consequent on the pregnancy; it was also probable that it might be an ovarian cyst which had twisted its pedicle. The tumour was very tender and the patient very ill, with a pulse-rate of 112 per minute and temperature 100° F. I opened the abdomen; the tumour proved to be a large subserous fibroid with a thick stalk; the uterus was gravid, and as it contained several fibroids the size of golf balls, I removed it. The patient recovered. (Case 19 in Table.)

On examining the big fibroid in the course of the operation I noticed an area of softening about 5 cm. in diameter; it appeared as if acutely inflamed, and there were flakes of lymph over this soft area. On completing the operation I packed the uterus and its tumours into sterilized waterproof material, and on reaching London took it to the laboratory for investigation. When the large subserous fibroid was bisected, a pyriform patch of red softening appeared (looking exactly like an infarcted area) equal in size to one-third the total bulk of the tumour, the remaining tissue of which was very hard. The red area had become so soft that the finger could be pushed in with ease. Mr. Somerville Hastings undertook the bacteriological examination of the red tissue, and he succeeded in obtaining in pure culture *Staphylococcus pyogenes aureus*, and the method by which he effected this is set forth in his own words: "With a piece of iron heated to redness a linear scar some 3 in. or 4 in. long was made on the peritoneal covering of the fibroid. A scalpel sterilized by prolonged boiling was then taken and an incision made deeply into the tissue of the fibroid by cutting along the seared area. The cut edges were retracted, and two small pieces of tissue about the size of peas were removed by forceps and scissors, also sterilized by boiling, from the centre of the fibroid and dropped into two tubes of ordinary peptone broth. These

were incubated at 37° C., and the next day staphylococci were obtained from both tubes. The staphylococci gave the staining and cultural reactions of *Staphylococcus pyogenes aureus*, and the cultures were shown to be pure by being plated out."

The interstitial fibroids showed the red changes in streaks, but no micro-organisms were isolated from them.

From the clinical standpoint red degeneration of fibroids associated with pregnancy is of great importance, and especially its influence in causing them to become tender and painful. It is necessary to emphasize the fact that these two signs—painfulness and tenderness—are only markedly exhibited by "red fibroids" when associated with pregnancy, and they are a source of errors in diagnosis. It is also necessary to state that pain is present only in the early stages of the degenerative process; when the tumour is completely disintegrated it is insensative. This is illustrated by examples taken from the uteri of women after labour, in which the degenerated fibroid is so soft that the finger can be pushed into it easily, and painlessly; but these softened submucous tumours set up profuse bleeding from the uterus and place the patient's life in great peril. This is a matter of some importance, because to my mind it is an explanation of the ready way

in which submucous fibroids complicating pregnancy so readily become septic during the puerperium and entail a long and dangerous illness, which often terminates in the death of the patient unless the nature of the case is recognized and the peril averted by a timely hysterectomy.

A uterus may contain many fibroids in its walls, yet only one will exhibit this red change and become acutely painful whilst its companions remain colourless and insensative. In one instance a uterus in which the pregnancy had advanced to the end of the second month contained seven fibroids varying in size from a golf ball to a duck's egg; three of them exhibited the red change.

The remarkable feature of the pain accompanying red degeneration is the suddenness of its onset. It is so sudden and severe that it resembles the pain experienced by patients when an ovarian tumour undergoes acute rotation and twists its pedicle, or the shock produced by the bursting (or abortion) of a gravid Fallopian tube. It is true that, in very many instances in which operations have been performed for fibroids complicating pregnancy, they were recommended and carried out on the notion that the patients were suffering from an ovarian cyst which had twisted its pedicle, or rupture of a gravid tube. In 1901 I published a table of 8 cases in which submucous fibroids had been removed from the walls of the gravid uterus on account of continuous pain, and in all the cases the operation was undertaken on an erroneous diagnosis. In many cases the fibroid was regarded as an ovarian cyst which had twisted its pedicle; in some a pyosalpinx; in others a gravid tube which had burst, for it must be remembered that the uterus and one of its Fallopian tubes occasionally become gravid simultaneously (compound pregnancy). It is only necessary to read carefully the "reports" of red fibroids communicated to the Obstetrical Section of the Royal Society of Medicine to learn not only how frequently the change occurs in fibroids complicating pregnancy, but how it produces symptoms which mimic those caused by the axial rotation of ovarian

Fig. 1.—Uterus distorted with fibroids and containing a fetus of four months' development. From a primigravida aged 43. She recovered easily and quickly.

* The complete paper is published in the *Journal of Obstetrics and Gynecology of the British Empire*, April, 1909.

tumours, or the bursting of a gravid Fallopian tube, so that the most experienced practitioners of midwifery are often deceived.

The condition is being better recognised by obstetricians. It is clear that when a uterus beset with fibroids becomes gravid, the fibroids do not, as some believe, enlarge in consonance with the physiological increase of the normal muscular tissue of the uterus. That some of the fibroids enlarge is beyond doubt, but this is the result of interference with the circulation in these tumours producing oedema and colour change due to haemolysis of the blood, not to a rapid increase of muscular tissue, as so many writers have erroneously asserted. This is another illusion swept from obstetric art by careful microscopic inquiry. The student need only study the conditions which exist in the uterus depicted in Fig. 1 to appreciate the disturbance which the growth of the fetus must have produced in the "constellation of fibroids" by which it is surrounded. I removed that uterus from a primigravida, aged 43, on account of pain, realizing that she was pregnant, and that the acute pain and suffering which caused her to seek surgical aid were due, in all probability, to red degeneration of an interstitial fibroid, which could be felt as a tender uterine prominence in the hypogastric region. One tumour only in this uterus showed the red change; its companions exhibited the usual greyish-white tint common to hard fibroids.

It may interest you to know that even with the knowledge that the occurrence of red degeneration will produce pain, sudden and acute, like that accompanying rupture (or abortion) of a gravid tube, it is easy to make an erroneous diagnosis. The uterus represented in section in Fig. 2 illustrates this very well. I removed it from a primigravida aged 35, who had lived in sterile wedlock fifteen years. After over-running two menstrual periods she had a sudden attack of bleeding and painful seizures, which led the doctor to think that a miscarriage was impending. The bleeding continued, and at the end of three weeks the patient was placed under chloroform with the view of emptying the uterus, but a definite swelling could be felt in the right half of the pelvis which so simulated a gravid Fallopian tube that operative interference was deferred. Eventually the patient came under my care; the signs and symptoms accorded best with tubal pregnancy. Coeliotomy was performed. I found a gravid uterus containing many fibroids. A subserous fibroid as big as a bantam's egg and occupying the fundus of the uterus had swollen in consequence of red degeneration and split its capsule. There had been some bleeding into the abdomen, but nothing serious. The uterus was removed and the patient quickly recovered. The condition within the uterus is worth consideration, for there is a submucous fibroid projecting into its cavity. This tumour shows no degenerative change, but, as represented in the drawing, its capsule is enveloped with a thick layer of decidua.

I am particularly desirous to point out that when pain and tenderness, due to red degeneration of a fibroid, are present in a mild degree, they generally subside if the patient be kept at rest in bed. It is only the very severe cases which call for surgical treatment.

It is perhaps worth mention that a tumour occasionally grows in the ovary, which in its naked-eye characters, and even in presenting a whorled disposition of its fibres, resembles the hard uterine fibroid. The microscopical features of the "ovarian fibroid" are indistinguishable from those exhibited by the common hard uterine fibroid. The ovarian fibroid is also liable to soften, to liquefy, and to

calcify. As such a tumour may be met with at any age, from 17 to 77, it occasionally complicates pregnancy. An ovarian fibroid has been found incarcerated in the pelvis by a gravid uterus; when lying high in the abdomen above a pregnant uterus it has undergone axial rotation and twisted its pedicle, but in none of these adverse circumstances, so far as my experience shows, has red degeneration been observed. This is a matter worth attention from those who get the opportunity of examining such specimens, for if red degeneration is due to thrombosis, an ovarian fibroid with a twisted pedicle would be an ideal condition for its occurrence. I have on four occasions removed an "ovarian fibroid," each of which had been incarcerated by a gravid uterus, but none showed any signs of red degeneration.

In the early part of this lecture I mentioned, in referring to the overlapping of the child-bearing and the fibroid-growing period of a woman's life, that theoretically the coexistence of fibroids and pregnancy ought to be most frequent between the thirtieth and fortieth years. In order to test this I prepared the subjoined table, containing 20 consecutive cases of this unfortunate conjunction, which have come under my care since 1900.

The facts are significant, for the patients, with two exceptions, were primigravidae. These women had in most instances married late in life, or, if they had been married many years, there had been a long interval of sterile wedlock (in one instance fifteen years). The pregnancies, with two exceptions, occurred after the thirtieth year of life. In the case of the two multiparae

the fibroid in each instance caused such severe losses of blood during the puerperium that an operation became an urgent necessity.

I have tested these points by reference to other cases under my care, and the conclusions are confirmed, so there is no reason to encumber the lecture or the reader with a longer table.

My knowledge of this red change in fibroids of the uterus complicating pregnancy is founded on a study of thirty-two examples which have occurred in my practice.

I hold no opinion as to its cause. The presence of micro-organisms in the degenerated tissue is in all probability exceptional; the thrombosis and the infarction theories require more proof. The only facts established in regard to red degeneration of fibroids is its proneness to occur in them when the uterus is gravid. Fibroids so changed seriously menace pregnancy.

ON THE SPONTANEOUS RUPTURE OF CYST-ADENOMATOUS OVARIAN TUMOURS.

By HENRY BRIGGS, M.B., F.R.C.S.ENG.,

PROFESSOR OF MIDWIFERY AND GYNAECOLOGY, UNIVERSITY OF LIVERPOOL.

THE main aim of this communication is to urge (1) that the primary cause of cyst rupture in cases of ovarian cyst-adenoma is tumour degeneration (necrosis), (2) that the rarity of cyst rupture in relation to the frequency of tumour degeneration is not inconsistent with the adequate vascular compensation almost invariably supplied by adhesions to the degenerated tumour, and (3) that these adhesions are simply reparative and are not, as generally stated, the result of peritonitis. The innocent leakage through attenuated and thin cyst walls, a common and normal occurrence, is distinguished from the rare rupture: on the absence in the former, or on the presence in the latter, of clinical manifestations is based a working distinction.

Cyst rupture as an appreciable clinical and pathological complication is one of the accidents in a case of ovarian cystic tumour, and just as in a case of accidental haemorrhage during pregnancy, trauma, or violence in the history of its causation, is almost invariably wanting.

The records from the earlier and darker days of ovariotomy of sixty-six and eighty tappings of an ovarian cyst leave no doubt as to the healing power of the normal cyst wall.

Meredith¹ reported an exceptional result of tapping in a case of his which became famous as evidence of the vital activity and resistance of the peritoneum; in a single woman, aged 47, after one tapping the refilled cyst ruptured and reruptured, into the peritoneal cavity, thirty-four times, and on each occasion with local pain and subsequent diuresis. At the end of a ten years' history the ovarian cyst, containing 21 pints of fluid, was removed with success; only a few filamentous adhesions around the aperture of the original puncture were found during the ovariotomy by Meredith.

Sir Spencer Wells² discussed adhesions after tapping; he stated that they were most frequently absent, and that there were firm adhesions in some patients who had never

been tapped; the mortality table of 500 cases after one to eighteen cyst tappings proved that tapping itself had little adverse influence on subsequent ovariotomy in his hands.

The revival of tapping is not to be desired. Sir Spencer Wells said that during later years he became more impressed with the danger of putrefactive changes after tapping without antiseptic precautions.

In the absence of infective organisms and of loose particles of growth capable of implantation, intraperitoneal cyst rupture—at the time unattended by serious haemorrhage—is of itself a harmless, or almost harmless, pathological process; but, inasmuch as the opening from a degenerated cyst is permanent, the contents continuously dribble without any barrier of defence such as is provided by the haematocoele sac around a chronic tubal drip in a case of tubal mole. Hence, free intraperitoneal fluid (hydroperitoneum), devoid of any plastic properties, bathes on all sides the loose tumour.

Elsewhere,³ Dr. T. E. Walker and myself reported on the invariable absence of hydroperitoneum when adhesions were universal, whether with innocent or cancerous tumours and after torsion of the pedicle.

Cancerous tumours as a rule degenerate earlier, and adhesions are, or rupture is, earlier and more frequent than with simple tumours.

Degenerative changes are the common exciting causes of adhesions. Cyst rupture does not occur at the site of adhesions, but through unprotected degenerated areas of cyst wall. In Case 153 in Sir Spencer Wells's table of 1,000 ovariotomies there were, to portions of the tumour, parietal and omental adhesions, and there was, over other non-vascular, central portions of degenerated patches,

demonstrated in the same tumour, a covering of recent plastic exudate.

Where repair from without is defective the degenerated portions of the cyst wall may rupture. This is what had clearly taken place in the four cases of my series.

CASE 1.—A. H. A, Probe in Fallopian tube. B, Site of rupture.

CASE 1.—The aperture of rupture measured 3 in. by 1 in.; its edges were raised, everted, and adenomatous; the aperture led into a central cyst—half the size of the whole tumour—surrounded by tiers of small cysts; the small cysts contained thick, mucoid fluid. The whole tumour measured 7 in. by 7 in. by 3 in.; necrotic in many areas; two

patches of adhesions to bladder and rectum denoted early degeneration before the tumour—then the size of an orange—ruptured (vide infra).

A. H., aged 27; six years married; two children; each born by normal labour.

History.

Menstrual losses recurred fortnightly from the birth of the second child in August, 1906, to August, 1907—that is, for exactly one year; subsequent menstrual suppression continued for 16 months; epistaxis is stated to have recurred frequently and irregularly during the menstrual suppression. Dr. James (J. H. Preston), who sent the patient to me on January 20th, 1909, wrote: "The first abdominal pain, four months after the birth of her second and last child, was attributed to acute peritonitis; several weeks afterwards the abdomen was full of fluid; after tapping the abdomen, the tumour, the size of an orange, was felt; the intraperitoneal fluid reaccumulated with varying rapidity, and once there was a three months' interval between the tappings; latterly the large amount of over 2 gallons has been removed every fortnight or three weeks; the fluid has always been clear, pale in colour, and thin; specific gravity, 1005; only once a little blood was present; the oedema of the legs of a few months ago has not returned." The total number of tappings was fourteen.

Physical Examination.

January 20th, 1909. The abdomen had been tapped the previous day; 3½ gallons of fluid were then withdrawn. The

CASE II.—*Ruptured cyst: circular opening $\frac{3}{4}$ in. in diameter: cyst-adenoma of the right ovary, 6 in. by 6 in.*

M. A. D. (sent by Dr. F. J. Knowles, St. Helens), aged 26

Case II.—M. A. D. A. Site of rupture.

Case III.—M. G. Site of rupture indicated by an arrow. A, Photomicrograph.

flaccid state of the abdomen aided the palpation of the firmly cystic, lobulated, mobile tumour. The patient was feeble and emaciated; the flexure surfaces of her forearms were hollowed. Her strength was barely equal to the contemplated radical operation; she returned to Preston, in spite of entreaties not to waste time and not to allow the fluid to reaccumulate. She again came to Liverpool five days later and entered the Hospital for Women.

Operation.

On January 27th the abdomen was opened: 17½ pints of free fluid; specific gravity 1006; alkaline; mucin and protein present; probably a mixture of ascitic and ovarian fluids (Dr. T. W. Jones). The pedicle, 3½ in. wide, was laced through and through with No. 0 catgut. There were two localized adhesions to bladder and rectum.

After-History.

For a few hours she appeared to be dying; pulse 160; later she rallied appreciably, and the next day her condition was hopeful. On the fifth day Dr. McClellan, the house-surgeon, found a round and afterwards successfully treated a small carbuncle, 1 1/2 by 1 1/2 in., on the back of her neck. The highest temperature was 99.2°, on the fifth day after the ovariectomy, when the carbuncle was found; her pulse at that time remained at 120.

She is now well advanced in convalescence, in spite of a whitlow on the middle finger of her right hand, self infected from contact with the caruncle.

Case IV.—E. B. A, Site of rupture. p, Omental blood vessels.

six years married; three children, the youngest aged two years.

History.

History of ill health and increase in the size of the abdomen; she did not consult a doctor. During lactation for nine months after the last confinement there was menstrual suppression; menses afterwards regular until four months ago; since then the flow recurred fortnightly with pain. Throughout the whole day preceding her admission, from 9 a.m. onwards, the patient suffered from distressing vomiting, wrongly attributed to poisoning by uncooked plums consumed overnight.

Operation.

She was admitted into the Hospital for Women on August 18th, 1907 with fever, 100° F., pulse 120; irritable bladder and constipation. The abdomen was tightly distended and tender; there was free fluid and a tumour. On August 19th, the day after admission, the abdomen was opened; present in considerable ovarian tumour was removed; its pedicle was laced with cagut.

After-History.

A nightly rise of temperature of 100.4° F. for the first three days, and afterwards a normal temperature were recorded. The pulse fell from 120 to 80.

CASE III.—Cyst-adenoma of right ovary with circular opening of rupture $\frac{3}{4}$ in. in diameter: tumour 6 in. by 6 in.

Combined pregnancy and cyst adenoma:
large size without evident degeneration. Slight
emaciation.

M. G., a patient of Dr. Hugh T. Shaw, aged 50; single. Before the climacteric, at 44, menstruation had been regular. For two

years she had complained of sickness and weakness. Six months ago her abdomen was swollen. She has lost flesh. Abdominal pain at intervals. The abdomen contained free fluid around an ovarian cystic tumour. The fluid decreased in amount during the few days she was at rest in hospital.

Operation.

On November 14th, 1900, the abdomen was opened, and the thick ovarian intraperitoneal fluid and the ovarian tumour were removed.

CASE IV.—*Cyst adenoma, 8 in. by 5 in.: one heavy tumour, tensely cystic along the right and less tensely cystic along the left border.*

E. B., aged 42, twenty-six years married, three children, the youngest 10 years old.

History.

History of abdominal pain for one year; irritable bladder: menses longer in duration and shorter in interval. She had lost flesh. She was a sallow, anaemic woman. There was an adenomatous polyp of the cervix uteri; the ovarian tumour in the abdomen reached 2 in. above the umbilical level.

Operation.

At the operation on February 16th, 1909, the pedicle was ligatured and the whole tumour removed from amidst a pint of free ovarian fluid: the small aperture of recent rupture of the cyst and the dribble of its contents were observable through the large incision before the tumour was handled during the operation. Adhesions supplied by one omental band of blood vessels attached to the tumour some distance from the site of rupture.

A brief analysis of the four cases is suggestive. In non-malignant cyst adenomata the clinical manifestations are those of—

(a) Tumour degeneration: (1) impairment of health disproportionate to the size of the tumour; (2) abdominal pain; (3) variable distension of the abdomen; (4) irritability of the bladder; (5) irregular menstruation subject to the usual modifications of pregnancy, lactation, and the climacteric.

(b) Rupture of the cyst, acute pain, recurrent pain, vomiting, the accumulation at a variable rate of free fluid in the abdomen.

The diagnosis of cyst rupture by free intraperitoneal fluid can only be (1) positive, when the partially-filled cyst can be felt or when the previously firm cyst has completely collapsed; (2) presumptive, when the clinical manifestations of degeneration and rupture have been obtained; and (3) occasionally and exceptionally, when the free fluid is small in quantity and the rupture minute, both may escape detection before and during the operation of ovariectomy. The modern preference for removal of the tumour entire, if practicable, accounts for a long incision in Case iv, whereby both the 20 ounces of free intraperitoneal mucoid fluid, and the dribble through the small aperture of rupture were exposed to view.

The teaching of Matthews Duncan—that, although the diagnosis of an ovarian tumour approaches practical certainty, it is not one of scientific precision—applies also to the recognition of complications.

The ovarian tumours of small size and the largest of only moderate size in my series of ruptured cysts had impaired the health of the patients to an extent unusual for the size of each growth. Not one was malignant. The general peritoneum, so far as it was visible, was only changed in one case (i), in which it was injected and thickened, but not shredded.

The quantity of fluid in Case i may be estimated at 37 gallons, but it is not the fluid alone that exhausts the patient.

Records of tappings, as of other achievements during life, have been preserved in odd places. On the authority of T. Stafford Lee,¹ an old tomb (1728) in Bunhill Fields Cemetery, inscribed with the name of Dame Mary Page, who died at the age of 55: "In 67 months she was tapped 66 times, had taken away 240 gallons of water." Several similar epitaphs have been discovered. A dried ovarian cyst in the museum of the Royal College of Surgeons² is catalogued with this history: "Between 1757 and 1783, a patient, aged 27, to begin with, underwent 80 tappings, and lost 6,631 pints of fluid in 26 years."

The mechanical inconvenience caused to a patient by an abdominal tumour may be distressing. A multiple pregnancy or a combined ovarian tumour and advanced pregnancy entail physical inconvenience equal to that of an ovarian tumour of corresponding total size, yet the vital effects on the patient have always been widely different, as illustrated by the photographs.

Degenerative changes in cyst-adenomata are important; they frequently exist without clinical evidence, because the often slowly formed compensatory vascular adhesions they excite check or modify their course. Rupture is rare, and, like the degeneration of which it is the consequence, may occur early with a small growth, as in Case i, where the growth was the size of an orange.

Degeneration, whether the tumour be ruptured or not, varies in its effect on the patient with the degree of vital reaction she possesses, and with the total recumbent rest she takes; it may be revealed by corresponding clinical symptoms showing exacerbations or improvements. These variations are inconsistent with a locally progressive simple tumour, and they have not been shown to have been due to chronic inflammation.

THE INCIDENCE OF GONORRHOEA IN GYNAECOLOGICAL HOSPITAL PRACTICE.*

By FRANCES IVENS, M.B., M.S. LOND.,

HONORARY MEDICAL OFFICER FOR THE DISEASES OF WOMEN,
LIVERPOOL STANLEY HOSPITAL.

It is somewhat remarkable that a disease so widely spread in the community and disastrous in its effects upon the female pelvic organs should have been treated with less attention than the more rare gynaecological diseases. The explanation is partly the natural avoidance of an unpleasant subject. It is also probable that medical practitioners who are not regularly attending gynaecological departments do not fully realize the prevalence of the disease. Again, dread of publicity and possible litigation prevents frank statements from the doctor to the patient or patient's relatives. It therefore arises that the medical profession as a whole is somewhat indifferent on the subject of gonorrhoea, from ignorance of its prevalence, especially in the chronic forms.

Cases may be regarded as simple leucorrhoea, cystitis, or pelvic inflammation, unless a searching inquiry is made into their etiology. It follows that the lay public is entirely unaware of the lifelong suffering and chronic ill health caused to thousands of women annually by this infection. Otherwise it is inexplicable that while attention is concentrated on the falling birth-rate, no one should have brought forward gonorrhoea as the most frequent cause of sterility. Women are not infrequently blamed as unnatural creatures losing the maternal instinct in the present-day struggle for ease and pleasure when they are the victims of a preventable disease. The chief danger of gonorrhoea lies in its chronicity, as cases are multiplied by those who believe themselves to be cured.

Impressed by the relatively large number of cases of gonorrhoea in all stages presenting themselves for treatment in the gynaecological out-patient department of the Liverpool Stanley Hospital, I have kept brief notes for the purpose of getting some approximately accurate figures of the frequency of this disease in women.¹

It will readily be understood that a seaport, with its mixed nationalities and large proportion of sailors, would be in the unenviable position of being more generally infected than an inland city.

It is from 1,052 consecutive out-patients and 157 in-patients, drawn chiefly from the wives of dock labourers and sailors, that I have made notes on which I venture to base these statements. In many cases I have confirmed the clinical diagnosis by a bacteriological examination of the discharge from urethra, cervix, Bartholini's ducts, or of the contents of pelvic abscesses.

Diagnosis.

Most of the usual points have been considered—namely, a history of pelvic inflammation following the first menstruation after marriage, associated with painful micturition, sterility, and, when there are children, with the presence of ophthalmia neonatorum.

* Read before the Association of Registered Medical Women, March, 1909.

In getting the history, leading questions have not been asked, as it only adds mental misery to her physical sufferings if the suspicions of the patient are aroused as to the cause of the illness. In acute cases the physical signs are usually sufficiently striking, in latent cases there is more difficulty when the organism cannot be found. The presence of bilateral inflammation of Bartholini's ducts, shown sometimes by redness at their orifices, acuminated condylomata on the vulva, a caruncular condition of the urethral mucous membrane, may assist the diagnosis. In some of the more acute cases oedema of the cervical mucous membrane may cause a polypoid appearance at the external os. This may be followed by an erosion of the cervix with a yellowish-green vaginal discharge. The urethral lips may be swollen and oedematous. At the time of the menopause an irritating vaginitis sometimes occurs. When the disease is no longer limited by the internal os, but has spread to endometrium or tubes, a tender enlarged uterus, or an inflammatory mass in the pouch of Douglas, will be noted. The bilateral character of the lesions is not an infallible guide, as I have found the organism in a unilateral pyosalpinx, and a solitary Bartholini abscess.

Obscure cases of cystitis are frequently of gonorrhoeal origin, as the organism readily extends along the urethral mucous membrane to the trigone, and chronic ulceration results. Direct examination of the bladder and urethra by Kelly's cylindrical cystoscope with head lamp or forehead mirror is of the greatest value. In the knee-elbow position the bladder can be inflated with air and readily inspected. If a small-sized instrument is used no anaesthetic is necessary. At the same time, local treatment can be applied to the affected bladder or urethra.

Menstruation is usually increased in frequency and duration when the endometrium is infected. A mucopurulent discharge without menorrhagia is symptomatic of disease of the cervix limited above by the internal os. In quiescent cases menstruation is not infrequently followed by an exacerbation of the discharge, when the gonococcus can be more readily found.

A latent case may become acute after extreme exertion, exposure, during pregnancy, in the puerperium, or from any cause producing pelvic congestion.

Attempts at replacement of fixed retroverted uteri, pessary treatment, or curettage may cause an exacerbation in a latent case.

Incidence.

American and Continental observers have published statistics of the incidence of the disease, varying somewhat widely. Noeggerath,* who in 1872 was the first to point out the frequency of gonorrhoea, made some rather sweeping statements, which he modified later. Sanger³ estimated that 18 per cent. of all gynaecological cases had gonorrhoea. His facts were criticized by Erb,⁴ who found 4.5 per cent. of all married women affected among the cases he examined.

Statistics will vary with the class of patient, the character and religion of the population, and the personal factor of the observer. In the results here recorded I have not included doubtful cases.

Among 1,052 consecutive gynaecological out-patients I found 149 cases of gonorrhoea—14 per cent.—an incidence rather lower than that of Sanger. This means that one out of every seven women who come or are sent to the out-patient department has gonorrhoea in an acute or chronic form. Three cases of gonorrhoeal vulvo-vaginitis occurred in children. Nearly all the patients were poor, respectable, married women. Of them, 47 were sterile, 30 per cent., while a considerable number had only one child. I have not been able to ascertain the relative incidence of sterility in the pelvic or uterine cases and of those limited above by the internal os, though it might be of some value to ascertain if the latter condition affects fertility least.

Among 157 in-patients, nearly all operation cases, 39 were gonorrhoeal, or 24 per cent.—1 out of every 4 women admitted. Of these 13 were sterile, 33 per cent. Of these 39 cases, 5 required operation for purulent salpingitis, 2 for pyosalpinx, and 2 for ovarian abscess. In 2 there was a haematoma of the ovary, in 1 haematosalpinx. The latter condition was associated with haematuria and profuse cervical discharge. In 18 there was chronic salpingitis with adhesions from localized pelvic peritonitis. Among

them were 3 cases of hydrosalpinx. A large majority required laparotomy, 7 only, chiefly very chronic and long-standing cases of endocervicitis, were treated by curettage and the intrauterine application of pure carbolic acid. Among the total number have been some striking instances of the latent form becoming acute.

One patient after treatment for chronic pelvic inflammation became pregnant. She had a good deal of pain during the pregnancy and in the puerperium an acute exacerbation occurred necessitating later the removal of both tubes and the separation of innumerable adhesions.

A second case illustrates the danger of curettage for sterility. This operation had been performed at another hospital, acute symptoms immediately supervening. The patient declined further operation and was treated by a doctor at home for some months. When she was sent to the Stanley Hospital she had a large ovarian abscess extending nearly to the umbilicus.

A third patient, a widow, gave a history pointing to gonorrhoea fourteen years before. She had a small cyst of Bartholini's duct, and suddenly developed acute purulent salpingitis. It was possible that the organism had remained quiescent in the duct, but a second infection was also possible.

A fourth case emphasizes the danger of pessary treatment in chronic gonorrhoeal cases. In a young woman attending for pelvic pain it was possible after prolonged douching to replace a somewhat fixed retroverted uterus bimanually and insert a Hodge pessary. A week later she returned with an attack of acute purulent salpingitis necessitating operative treatment.

Curettage occasionally reveals the fact that what one has believed to be a limited endometritis has spread to the tubes.

A patient was curetted for supposed simple endometritis. Under the anaesthetic a questionable thickening of one tube was felt. The next day there was a high temperature with symptoms of pelvic peritonitis, which fortunately rapidly subsided.

Curettage should be limited to cases of endocervicitis, where the infection has not spread beyond the internal os.

The Gonococcus.

The gonococcus, though difficult to cultivate, can be fairly easily recognized in smear preparations from its morphological characters, staining reactions, and tendency to penetrate the protoplasm of the leucocytes. In pus of long standing the gonococci may be absent or scanty, and when found look unstained and degenerate. Secretion from urethra, cervix, or Bartholini's ducts gives the best results. The organism has a tendency to linger in recesses lined by columnar epithelium.

Mortality.

In this series of 37 in-patient and 149 out-patient cases there has been no death.

Prognosis.

Once infected the prognosis as regards cure is uncertain. Even when the disease is confined to the lower zone—that is to say, is limited above by the internal os—it is possible for the organism to lurk in a recess and to cause further trouble. In pelvic cases complete recovery without a mutilating operation is uncommon, even when prolonged rest can be taken. Conservative efforts directed towards preservation of the tubes frequently end in disappointment and a second operation. Still, the occasional success of such efforts is an encouragement to refrain from unnecessarily severe measures. In most cases the patient, if a young woman, prefers to run the risk if the facts are explained to her. Reinfection frequently spoils a successful course of treatment. One patient curetted for long-standing leucorrhoea was quite well for six months. She then returned with an exacerbation apparently due to a reinfection.

In a mild case the prognosis is difficult. The disease may subside to light up again after extra exertion or during menstruation or pregnancy. In many cases the patient becomes the subject of chronic pelvic pain, which takes her from one hospital to another. The physical signs are so slight that she is often regarded as the victim of neurosis, and it is only on opening the abdomen that one finds justification for her complaints. In such cases operative measures are often quite successful, and, freed from the chronic pain, the nervous system may return to a normal condition.

Treatment.

The treatment of these cases has necessarily varied with the character and site of the disease. If acute, rest and

cleanliness have been the first measures adopted. Alkaline sitz-baths have been advised, to relieve the pain and remove the discharge.

In chronic bladder lesions, the local application of silver nitrate solution through a Kelly's speculum, followed by boric lotion irrigation has given good results.

Caruncular excrescences of inflammatory origin have been snipped off and the bases canterized, and similar treatment has been applied to acuminate condylomata.

Cases of acute salpingitis have been kept in bed until the temperature fell, on milk diet, saline aperients, having turpentine stupes applied for the severe abdominal pain. If pus was suspected, the abdomen was opened. In all but one case, at least one ovary has been left.

This patient, a young woman, came up a few months later looking very miserable. She said she had no pain, but felt wretched, was irritable, had pains in her head, and was getting thin. She improved on tonics to a certain extent. The operation had been for a prosalpinx which had undergone torsion with resulting haematosalpinx. The other tube was diseased, and so intimately associated with the ovary that removal was necessary. The uterus was left.

It has been occasionally possible to excise the inflamed corpus luteum containing sero-purulent material by a wedge-shaped incision, leaving healthy ovarian tissue, and such cases have done well.

Expectant treatment has been adopted when the acute attack passed off rapidly, and the physical signs were slight. Unfortunately cases of complete recovery have been few, a relapse often driving the patient back into hospital. After a sharp attack, when the patient has to return to hard household labour, such as washing, it has proved more satisfactory to open the abdomen, and then to treat them as conservatively as possible.

In two of the 39 cases the uterus was removed with the tubes.

In one case an ovarian abscess communicated by a small fistulous opening with the rectum, and was secondarily affected by *B. coli communis*. All the pelvic organs were matted together by adhesions of some eighteen months' standing, and the uterus was removed for vaginal drainage. It was easier to remove than to leave it.

In a somewhat similar case of large ovarian abscess the wall had become adherent to the bladder, into which it was on the point of discharging. With some difficulty on account of the infiltration at the base of the bladder the uterus was removed with the tubes and right ovary, no rupture of the abscess taking place. As there was danger of leakage from the bladder, the pelvis was drained with iodoform gauze carried through into the vagina. The uterus was large, and its lining resembled the wall of an abscess cavity.

In both these cases the pouch of Douglas was opened up posteriorly to avoid leaving an undrained cul-de-sac. The after-result in these cases was better than in those in which the uterus was left, where leucorrhoea often persists.

Drainage has not been adopted in gonorrhoeal cases, unless there has been some complication, and only in one instance through the abdominal wall, where there was suspicion of injury to a ureter in a myxoedematous patient, whose condition did not warrant prolonging the operation. Drainage has proved to be entirely unnecessary, and, after mopping out the pelvis with warm saline solution on gauze sponges, the abdomen has been closed.

One case subsequently developed a small pelvic abscess, necessitating drainage, following the removal of a thickened tube and ovarian haematoma.

She was a very anaemic and debilitated woman. The abscess was so small that it could not be localized from below, and was reached through an incision above Poupart, through which adhesions were separated. Two fingers in the vagina were of assistance in locating the pus, the quantity of which did not exceed a teaspoonful.

In all cases the abdominal wall was sewn up in three layers, with fine catgut for the peritoneum, and buried continuous silkworm gut for the sheath of the rectus. No hernia has at present been reported, though belts were not advised, and the patients got up about the tenth day, leaving on the twelfth, unless there was some contra-indication. No suppuration in the abdominal wound occurred in any of these cases, except in that of the pelvic abscess, where the silkworm gut was removed at the second operation. It would appear that a high opsonic index has been reached, and that the tissues are highly resistant to microbial infection.

It is too soon to give complete after-histories. At present a considerable number have reported themselves as quite well. In three or four some chronic pain remains, and these are unfortunately those in whom adhesions were separated, leaving what were to all appearances healthy tubes. Leucorrhoea has persisted in some instances where the uterus was left.

Prophylaxis.

My object in bringing forward these facts is to renew interest in a disease extremely widespread, and the cause of endless suffering to many ignorant and innocent women, and in the hope that practical prophylactic measures will be suggested.

I would suggest that, with the co-operation of the medical profession as a whole, further investigations be undertaken to ascertain the extent of this disease, and some attempts made to lessen the incidence.

I do not venture to indicate how to deal with the sensitive social conscience of the present day, but it is obvious that ignorance constitutes a grave danger to the community.

Loyalty to the patient herself must be the first consideration, and the risks employers and others are running secondary. Apart from education, the only solution of the problem is notification, as has been suggested for ophthalmia neonatorum, so that early and complete treatment could be adopted and if necessary enforced. To this method, unfortunately, there are many grave objections.

CAESAREAN HYSTERECTOMY IN PREGNANCY COMPLICATED BY MYOMA UTERI.

By JOHN BENJAMIN HELLIER, M.D.,

PROFESSOR OF OBSTETRICS IN THE UNIVERSITY OF LEEDS AND OBSTETRIC
PHYSICIAN TO THE LEEDS GENERAL INFIRMARY.

A good deal has been written lately on the treatment of myomata in pregnancy. My experience in Leeds confirms the view that operative interference is very rarely called for to secure delivery. The myoma very rarely obstructs the birth. When, however, the parturient canal is seriously obstructed, operation is necessary to save the child and to obviate risks to the mother. When anatomical relations permit, myomectomy is the operation to be preferred, but in most cases that require operation hysterectomy is best.

CASE I.

Mrs. A. B., wife of a medical man, was brought to me by her husband in July, 1908, on account of myomatous growths in the pregnant uterus. She was 35, and had been married six years without becoming pregnant; she had enjoyed good health on the whole, and, though liable to dysmenorrhoea, had never suffered from menstrual excess. She had not suspected that anything was wrong with the uterus until a few weeks pregnant. Menstruation ceased in April, 1908, and labour was due about January 22nd, 1909. The usual symptoms of pregnancy were present when I saw her, but the uterus reached two-thirds the distance between pubes and navel in the third month, and there was a hard myoma on the right of the fundus. On vaginal examination, another could be palpated occupying the posterior and left wall of the cervix and projecting in the direction of the broad ligament. It was clearly recognized that this might prove an obstacle to normal delivery, but it was decided to let the case go to term if possible. The husband was very anxious that the child should be saved and that delivery should take place *per vias naturales* if possible, and that later the myoma should be operated upon, for he was contemplating removal to a foreign station, and very much dreaded the possible recurrence of the conditions now present at a time and place where skilled assistance might not be available. I willingly agreed to do my best to carry out his wishes, but stipulated that if at any time the parturient canal were found to be seriously obstructed I should be at liberty to perform Caesarean section and deal with the myomata at the time as might seem best. What one would most anxiously avoid would be to allow labour to progress to the second stage and then to be compelled to destroy the child, or to risk damage to the myoma and uterus, or else to have to perform Caesarean section on a patient advanced in labour after fruitless efforts at vaginal delivery. This discretion was freely given by those concerned.

In the following month the uterus increased rather quickly in size, and there were at least two attacks of severe pain, with symptoms of obstruction of the bowels; fortunately these yielded to simple treatment. During the autumn there was a good deal of pain in the left leg, and vomiting was troublesome.

In spite of our fears to the contrary, she went to term, and when she came into a nursing home on January 20th I was delighted to find her in very fair condition and free from serious symptoms. There could, however, be no doubt as to treatment, for the head was mobile above the pelvis, and could not be made to enter it, while a large, solid tumour occupied the pelvis and could not be pushed up. The liquor amnii began to be discharged on January 21st.

Operation.

The operation was performed on January 22nd. Mr. Hann administered chloroform, and Mr. L. R. Braithwaite assisted me. Through a median abdominal incision I drew the uterus forwards and removed the child by an incision in the fundus. On drawing up the uterus I was glad to find that below the myoma in the cervix there was space for a satisfactory supra-vaginal amputation. The right ovary was not removed. I tied the vessels with catgut, drew the edges of the stump lightly together with a few catgut sutures, and sutured the peritoneum over it in the usual way. No drainage was necessary. The myoma was then closed as usual.

This operation, which has superseded the old Porro, is to any one accustomed to hysterectomy a quick and easy one, for the size of the abdominal incision and the laxity of the tissues make it very easy to see and deal with all the parts concerned. The child was a very well developed male weighing 8 lb., and having a chest girth of 18 in. Except for a little temporary difficulty on the second day with intestinal distension, which yielded to treatment, the mother made an uneventful recovery. She had an abundant supply of milk, and suckled the child entirely from the fourth day onwards; the wound healed without suppurating, and the husband was able to take her home at the end of two weeks. She has progressed well since, and the child has gained on an average about 4 lb. a week.

The specimen removed was shown at the Leeds and West Riding Medico-Chirurgical Society on May 7th; it measures after retraction and hardening 12 in. by 7 in. It shows three myomatous nodules in the corpus uteri, and one as large as a fetal head in the cervix. It does not project into the cervical canal, and could not have been removed by the vagina before delivery. A portion projected downwards towards the sciatic notch, and probably pressed on the nerves.

CASE II.

This bore a close resemblance to Case I. A woman, aged 31, married three years, primigravida, was brought to me, when three months pregnant, by Mr. H. J. Roper of Leeds, in July, 1908. She was a spare but not unhealthy woman, and had suffered from no serious degree of menstrual excess. The myomata had never been discovered before pregnancy. The uterus reached nearly to the navel, and at least felt as distinct and rather mobile myomata could be felt through the abdominal wall.

Per vaginam several nodules could be felt in the lower uterine segment, threatening obstruction in labour, although not so great as in the last case. The usual signs of pregnancy were present. Labour was due about January 18th, but she did not go quite to term, but came into the nursing home on January 6th with the liquor amnii discharging.

Operation.

The operation was performed on January 7th, its details being almost exactly the same as in the previous instance—supra-vaginal amputation, right ovary not removed, retro-peritoneal treatment of stump, no drainage, no difficulties. The child weighed 5 lb. 7 female. The mother was not able to suckle through failure of secretion. The wound healed without suppuration, and the recovery was uncomplicated.

The uterus removed shows an extraordinary number of interstitial, subserous, and submucous nodules; there must be about twenty in all, larger or smaller. One of the submucous nodules was almost detached in the uterine cavity. There was no appearance of degeneration in the myomata.

I may refer, in closing, to a case on which I operated several years ago, where a myoma complicated a four months' pregnancy and was causing pressure symptoms. It was felt in the pouch of Douglas, and was supposed to spring from the cervix and lower part of the uterus. It turned out to be a myoma springing from the fundus of a retroflexed pregnant uterus, and could be drawn out of the pelvis on abdominal section. The uterus is now in our museum, and the case illustrates a difficulty in diagnosis which is worth noting.

The safety of modern Caesarean section, whether conservative or mutilative, is so well established as to need little emphasizing, but I think that there are many women with a sufficient degree of pelvic contraction to lead to loss of child after child who might well be encouraged to undergo delivery by abdominal section for the sake of having a living child.

UNDER the will of the late Miss Ann Hill of Peterborough, who died on March 20th, the Hunstanton Convalescent Home and Peterborough Infirmary each receive a sum of £2,000. They are also entitled to share in the residuary estate, and from this source will probably each receive some £700 or £800 in addition.

A SUCCESSFUL CASE OF HYSTERECTOMY FOR PUERPERAL INFECTION.

By A. KNIVETT GORDON, M.B. CANTAB.,

MEDICAL SUPERINTENDENT OF MONSALL HOSPITAL, MANCHESTER.

In my own experience it is very rarely indeed that the question of performing hysterectomy for puerperal septic disease presents itself. In a series of 250 cases of the more severe type of puerperal fever, I have only attempted the operation once with a good prospect of success in the following case, though I have removed the uterus unsuccessfully in 5 other cases (twice by the vagina and three times abdominally) as a last resort and at the urgent solicitation of the relatives or of the medical attendant. As a rule, the patient is either in a condition of general septicæmia with streptococci in the circulating blood when she arrives at the isolation hospital, or if the lesion is well localized, reacts to vigorous disinfection of the uterus.

F. G., aged 23, a previously healthy primipara, was delivered at full term of a normal child on August 21st, 1908. A midwife only was in attendance, who is stated to have made vaginal examinations very frequently until the birth of the child, the labour lasting thirty hours. Half an hour after delivery, the placenta having partially come away, there was severe post-partum hæmorrhage, and a medical man was summoned, who found it necessary to introduce his hand into the uterus in order to detach the remains of the placenta. He did not wear gloves, and was unable, owing to the absence of any facilities, to disinfect his hands, or even wash them satisfactorily. Half an hour later, as the bleeding recurred, he repeated the manoeuvre, and then gave an intrauterine douche.

Sixteen hours later the temperature rose, and the patient had a rigor. She became rapidly worse, and ultimately—seventy-two hours after delivery—was notified as a case of puerperal sepsis and removed to Monsall Hospital.

Condition on Admission.

Her state was very grave. The pulse rate was 144 and the temperature 103°. The extremities were cold, and there was intense anaemia with much prostration. The abdomen was uniformly distended but there were no signs of general peritonitis; the fundus uteri could be felt externally 1 in. above the umbilicus. On further examination the vagina was found to be sloughing, with large necrotic masses on each labium and on the posterior wall. The cervix was split bilaterally, and the posterior lip was covered with greyish membranous exudate. The os was widely dilated, and fetid pus was flowing freely from the interior of the uterus, the cavity of which measured no less than 10 in. in length. The uterine wall was everywhere softened, and it would have been possible to push the finger through its substance without difficulty. At the fundus were several partially loose masses of placental tissue.

The advisability of removing the uterus forthwith was considered, but as the patient was worn out from want of sleep and in a very dirty condition from the absence of proper attention, and as it also appeared desirable to investigate the bacteriology of the blood before operating, I decided to temporize. Accordingly, under the analgesia afforded by a dose of alcohol followed by morphine subcutaneously, I scraped the interior of the uterus thoroughly with a large sharp curette, and swabbed the resulting raw surface with pure iodo solution, packing the cavity subsequently with gauze soaked in a 1 in 100 solution of the same preparation. Three pints of saline solution were then given subcutaneously.

Operation.

On the morning of the next day the patient had rallied somewhat, but the pulse-rate had not diminished, and the temperature remained at 103°. Two rigors had occurred. The cultures taken from the blood showed no growth (and remained sterile subsequently), while those from the interior of the uterus showed *B. coli* and *B. proteus* in large numbers. I came to the conclusion that there was no general bacillary infection, and that it would probably not be possible adequately to disinfect the uterus by further local palliative treatment, so I opened the abdomen and amputated the uterus at the level of the internal os, leaving both ovaries, and covering the stump with peritoneum in the usual manner. A rubber tube was placed in the remains of the cervix, and the peritoneal cavity closed without drainage. After the effects of the ether had passed off the patient was propped up in the sitting position, and three pints of saline solution given subcutaneously.

After-Treatment.

For the next ten days the temperature remained at about 101° until the discharge of pus from the cervix and sloughing vagina had ceased, but her progress after the operation was otherwise very favourable. She left the hospital sixty days after the operation with a firmly healed abdominal wound, and free from vaginal discharge. A month later I saw her again, and found the vaginal vault firmly healed. She had resumed her work as a tailoress, and had menstruated since her discharge.

I have only to add that the reason why I did not remove the cervix as well as the body of the uterus was because the patient's condition rendered it desirable that the operation should not be prolonged. In this case it had lasted for twenty minutes, and it then seemed that the further ten minutes or so which would be required to remove the cervix might turn the scale against the patient. On theoretical grounds, however, I should prefer the total operation in a similar case.

"CLEAN MIDWIFERY" IN GENERAL PRACTICE.

By ARTHUR H. GREGSON, M.B., CH B.,

BLACKBURN.

For five years no doubt had ever entered my mind as to the efficacy of mercury perchloride as a hand and labial disinfectant and a sure preventive of puerperal fever; but in December, 1905, a midwife sent for me to attend one of her septic cases, which proved fatal within a week; and after that, though none were fatal, several of my own had unpleasant rises of temperature; it seemed as though the infection would not be got rid of, so I determined to use rubber gloves.

At first they were carried in a glass bottle containing glyc. ac. carbolic, diluted ten times at one end of my bag; a yard of cotton-wool was also put in, and the midwifery forceps transferred to a sterilizer made by a local tinsmith for 7s. 6d. The nurse was required to find an enamel pan and some soda to boil the gloves, a bowl for lysol to transfer them to, another for perchloride to wash the labia with, as the lysol is too irritant, besides the usual washhand basin, the whole making a somewhat formidable array.

Before long, however, a case occurred in which elaborate preparations were out of the question; even a pint basin for the perchloride had to be borrowed—just such a case where perfectly clean midwifery would be held an impossibility. In these poor houses the gloves are put into the kettle and transferred to the mercury solution instead of to lysol, and this is found to do quite well. Of course the soda is omitted, and then the gloves must be boiled in it at home to remove any trace of blood or fat before being used again; whereas this is usually done at the patient's house, the pan being kept at one side throughout the case and used repeatedly.

The gloves having been boiled, one's own hands are washed with soap and water, all the folds of the patient's genitals and adjacent parts cleansed with perchloride and the vagina swabbed as thoroughly as possible with cotton-wool wet with the same solution and never dipped into it a second time; then one's hands are sterilized in the ordinary way and the gloves put on without filling with water, a pad of cotton being used to work them on, and the examination made without any lubricant except the 1 per cent. lysol when convenient, contamination from the anus being prevented by keeping a pad of dry wool over it. The patient is always instructed to have an enema before she sends for me, but too often she omits it. If during the vaginal examination the rectum is found overloaded and the os not fully dilated, an enema is given.

If instruments are found to be required, boiling water is poured into the tin, the gloves put in, and 2 per cent. lysol added. The whole are then boiled for five minutes with the spirit lamp, half the solution poured into a jug as a reserve, and cold added to the tin.

Such a change in routine had its disadvantages. Tactile sensation required re-educating, but half a dozen cases were sufficient to complete this. The waste of time was at first about an hour, but now it is only fifteen minutes, and is fully compensated for by not having to give intra-uterine douches later. If any rotating or turning is required, lysol makes the gloves too slippery, and perchloride must be used instead.

The greater peace of mind is worth much, although two or three cases of puerperal fever have occurred in my own practice since.

The first was one in which the patient had taken plenty of castor oil, and refused to have an enema, with the result that faeces contaminated my glove during the

rotation of an occipito-posterior into an occipito-anterior presentation, and taught me to leave the pad at the anus.

The second might easily have been a mystery, but that on my arrival a neighbour said, "She won't be long now, doctor." "You have examined her?" I asked. "Yes, but my hands are clean; I am washing," she answered. A washerwoman making a vaginal examination! In this case the mother-in-law remarked, "There should be no blood poisoning here," when she saw my preparations to prevent it.

The third was an occipito-posterior presentation delivered by rotation and instruments; the perineum was torn. There was swelling of the abdomen six hours later, which disappeared after defaecation next day. The temperature never rose above 99.6°, and became normal after removing a painful suture on the fourth day; the pulse fell from 108 immediately after delivery to 80 during the same time. Satisfactory progress reported on the seventeenth day. At noon on the eighteenth day I was called in again. She had vomited; was suffering from pain in the right iliac region; the temperature was 102°, and the abdomen again swollen. On vaginal examination there was tenderness limited to the right fornix; an intrauterine douche brought away nothing and caused no improvement. Involuntary defaecation commenced soon after, and a rigor occurred on the twentieth day. A consultation was held on the twenty-first day; the uterus was normal for the time, and the perineum healed, but the abdomen was more distended. Septic peritonitis was diagnosed, and the appendix mentioned as a possible source; but, owing to the circumstances, it was decided to regard the genital canal as the route of infection. She had always been much troubled with wind—a complaint which I remembered (when too late) that two of my male patients have recently been completely cured of by removal of the appendix.

Patients themselves like the gloves, because they slip in more readily than the bare fingers, and one commented that I had not scratched her.

The greatest enemies were the neighbours, who declared unanimously against the innovation, one admitting that she had not sent for me "because Dr. Gregson is so faddy"; another asking if I was afraid of blood; but the most annoying incident was the setting out of the report that a certain patient must have had syphilis, or gloves would not have been used, after which I put up a notice that an extra charge of 2s. 6d. would be made for rubber gloves.

Memoranda :

MEDICAL, SURGICAL, OBSTETRICAL.

PRIMARY EPIDIDYMITIS IN MUMPS.

On the evening of April 16th, 1909, I saw a youth, aged 18 years, lying in bed and complaining of a pain in the right testicle. This on examination proved to be due to epididymitis, the body of the testicle being quite sound. The temperature was 99.4°, and the history of the onset quite sudden and non-traumatic.

There was no urethral discharge or scalding, nor had there been any; the boy (a country lad) denied any sexual history, nor was there anything about the meatus urinarius to cause me to doubt the truth of his statement. I recommended supporting the testicle on a pillow covered with mackintosh, and hot fomentations, giving at the same time a saline purge. The next day the true nature of the case revealed itself. The left parotid swelled out in the typical way, and also the right submaxillary gland. The temperature rose to 103° and a little over. The body of the testicle began to swell the following day. In about ten days the fever and swelling subsided, and salivary glands and testicle resumed their normal appearance.

The unusual feature of the case is the primary manifestation in the epididymis. The so-called metastatic orchitis frequently precedes mumps, but in no case can I find a record of the epididymis taking the lead. The testicular manifestations are almost invariably unilateral and are frequently followed by atrophy of the gland, which fortunately did not occur in this case.

Whittlesey.

J. J. WADDELOW, F.R.C.S.Eng.

THE TREATMENT OF BOILS AND CARBUNCLES. No boil or carbuncle need be painful, nor should the treatment cause pain. I recently gave gas for a friend who opened and scraped a very painful boil on a man's arm. The treatment was drastic, it may have been efficacious, I do not know, but it certainly was painful. Not long previously I had treated a glycosuric man for one of a series of large boils on his neck. The previous boils had been cut or scraped *secundum artem*, and had caused great pain.

The treatment which I employ is simple. A pledget of cotton soaked in carbolic glycerine is applied to the boil and covered with gutta-percha tissue and a bandage. As soon as pus shows, the epithelium is gently turned back and the glycerine reapplied. As soon as a slight cavity appears some of the glycerine is gently inserted by means of a simple glass syringe, and again the poultice of glycerine is applied. In two or three days the slough separates, and after one final poultice of glycerine the cavity speedily closes, with the minimum of scar, under any simple dressing. The hygroscopic action of the glycerine relieves the tension—the cause of the pain—very speedily, and it need never recur.

I have never had occasion to use any other treatment. I have never seen a carbuncle spread when once this treatment was begun, still less have I seen any danger to life in my own cases.

One very serious case I saw recently in consultation—that of a butcher with a carbuncle 6 in. by 4 in. between the shoulders. The treatment described above was adopted, the spread of the carbuncle was promptly arrested, and a quick recovery ensued.

My glycosuric patient tells me he has had more than one boil since, but has not needed my help as he independently treated himself in the same way.

This method is not original. I owe it to my old teacher, the late Dr. John Duncan of Edinburgh. It may be that glycerine alone would suffice, but I have no fear of the carbolic acid, as the glycerine dehydrates the tissues and so probably prevents absorption.

London, E.C.

A. OGIER WARD, M.D.

TETANUS FOLLOWING SURGICAL OPERATIONS. I HAVE been deeply interested in the excellent paper by Mr. W. J. Richardson on the subject of tetanus occurring after surgical operations, and in the subsequent contributions by other writers on the same subject. I have personal experience of one case that occurred at the Ingham Infirmary, South Shields, in March, 1907, where I was at the time senior house surgeon. At the request of the surgeon who operated, I sent complete notes of the case very soon after it occurred to the *Northumberland Medical Journal*. It also formed the subject of a very prolonged and very interesting discussion by the Newcastle-on-Tyne Medical Society. I have unfortunately mislaid the notes of the case and the journal in which it was published; but I have been favoured by the Secretary of the Clinical Research Association with an exact copy of the report on the examinations made for me, and I believe I can give the other details fairly well from memory.

The patient was a woman, about 31 years of age, and the operation was ovariectomy. Everything went well from the time of the operation, the wound healed by first intention, and the patient was making an excellent recovery. About the seventh or eighth day after the operation she began to complain of pain and stiffness in the back of the neck, a little later this was followed by stiffness in the jaws and difficulty in opening the mouth. This condition advanced very rapidly, and within a few hours from the onset of the first symptom I came to the conclusion that she was undoubtedly suffering from tetanus. I started antitoxin treatment immediately, but in less than thirty hours from the commencement of the trouble she was dead.

I at once drew off some of the cerebro-spinal fluid and sent it to the Clinical Research Association of London for examination, but nothing specific was found. The catgut was suspected. We had at the time four varieties of catgut at the hospital from four different firms. The catgut used in that particular operation came from a stock we had just got in and which we had only then used for the first time. I may also say that to the best of my recollection it came from a firm—I remember the name of the firm—that supplied us then for the first time. The method of sterilizing in that particular case was the same as had been in practice at the hospital for a considerable number of years. I took samples of the four varieties of catgut, marked them A, B, C and D, and sent them to the Clinical Research Association for examination, which was carried out with great precaution and

every possible attention to detail. I quote here from their report.

"Several varieties of sporing bacilli, including atrophic as well as anaerobic organisms, were obtained from the various samples, but it was only in 'D' that an organism having the characters of the *Bacillus tetani* was found. . . . From the cultures of this sample 'D' of catgut we have isolated a large anaerobic bacillus, of which certain of the individuals show large terminal spores, giving to the rod the drumstick appearance characteristic of the *Bacillus tetani*."

A note was added to the report to the effect that it would not be possible to find proof of the specific nature of the bacillus without animal inoculation, and that they were not authorized to make an animal experiment made—this a triumph for antivivisectionists!

It only remains for me to add that sample "D" of the catgut came from the stock we had used in the operation here described, and I regret very much that the investigation was not carried further, and an animal experiment made.

London, N.

J. I. JAFFÉ, M.R.C.S., L.R.C.P.

POISONING BY BISMUTH SUBNITRATE INJECTED INTO A KNEE-JOINT.

IN view of the frequency of bismuth injections into cavities for diagnostic purposes by radiography, the following note may interest surgical readers:

P. E., aged 37, with a history of venereal trouble and joint affections but no injury, came under my care on March 8th. His right knee was swollen, and had been getting sorer and larger for two months. Several examinations of the fluid, which was at first purulent and later serous with some stringy fibrous clots, revealed no organism, either by culture or microscope. Calmette's test gave a slight positive reaction. As the serous discharge was rather profuse, I injected over 2 oz. of a 1 in 3 suspension of bismuth subnitrate in vaseline on April 12th. A rather tight bandage was applied, and in thirty-six hours a characteristic bismuth stomatitis with ulceration developed. There were no digestive symptoms except anorexia. The joint was evacuated, and the ulcers in the mouth healed up in a week, with the help of a feeble acid mouth wash and free use of swabbing with a solution of potassium chlorate. There was no looseness of the teeth. The joint also rapidly improved, and the knee was quite well to appearance and painless three weeks later. There was still some coloration round the teeth and gums when he left hospital.

DEVON COUNTY ASYLUM.

A CASE OF SUDDEN DEATH FROM PANCREATIC HAEMORRHAGE.

(Reported by SIDNEY J. STEWARD, M.B., B.C. Cantab.,
Assistant Medical Officer.)

THE patient in the following case, a man aged 65, had been in this asylum for seven years, suffering from depression with intermittent insomnia.

History.

During the last two years he became partially demented and had a delusion that something was wrong with his testicles, which he wished to have cut away. There was never any indication of organic physical disease, but he was always rather thin and sallow, with flabby muscles and a small, soft pulse. Being suicidal he was under constant observation, and his bowels and bladder were seen to act regularly; he ate well, did not vomit, and seemed in his usual state of health up to the time of his death.

He got up at 6.30 a.m. and dressed and washed himself, and at 7.30 a.m. he was seated in a chair, being tidied, when he suddenly fainted in the attendant's arms; he became pallid, cold, and pulseless, and died in two or three minutes, with no other symptoms than those of syncope.

Necropsy.

At the necropsy the pancreas was found to be totally disorganized by recent blood clot, which involved the surrounding tissues and the suprarenal capsules. Under the microscope these glands showed recent infiltration with blood, but there was no evidence of inflammatory change, fat necrosis, or new growth. The only other pathological conditions found were marked congestion of the lungs, liver, and spleen; a few minute cortical cysts in the left kidney, and one as large as a hen's egg in the right; a patch of old pleurisy on the right side; some thickening of the parieto-frontal pia arachnoid; slight degeneration of the cardiac muscle, the valves being competent. There was no pigmentation of the skin, no oedema, and no sign of trauma, and the urine drawn from the bladder *post mortem* did not reduce Fehling's solution.

REMARKS.—Death was apparently due to a haemorrhage into the pancreas, which involved the suprarenal capsules and the surrounding areolar tissue, and seems to have occurred spontaneously, as there was no evidence of any inflammatory change, new growth, or traumatism.

Reports of Societies.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

Thursday, June 10th, 1909.

Mr. W. H. H. JESSOP in the Chair.

Congenitally Defective Lenses.

Mr. P. H. ADAMS described a series of cases of congenital displacement of the lens. The patients were a mother and seven out of her nine children. No other instance could be found in the family. In three cases the lens was displaced downwards, instead of the more usual displacement upwards, while in the eldest boy the dislocation was complete, thus leaving the pupil clear of the lens. The two members of the family who were unaffected had perfectly normal eyes. He also dealt with a family with congenital opacities in the lens. The great-grandfathers, grand-mother, father, and four of his children (out of five), as well as the father's sister, showed the peculiar opacities of the lens known as stellar cataract. Posteriorly there were from three to six primary rays, and numerous secondary ones, while some of them showed Y-shaped markings on the anterior surface as well. The opacities slowly increased throughout life, especially in the front of the lens, while the posterior markings were broader and less defined.

Retinal Disease.

MESSRS. A. HILL GRIFFITH and A. W. ORMOND read a paper entitled, *A Case of Retinal Disease, with Massive Exudation and Arterio-venous Communication*, the patient being a woman aged 31. The left eye had been removed for secondary glaucoma by Dr. Hill Griffith ten years ago. The fundus of the remaining eye showed very tortuous and distended retinal vessels, with varicosity of several of them, and a red blurred optic disc. In the extreme periphery of the fundus, deep to the retinal vessels, was a whitish mass, the limits of which could not be seen. The changes in the fundus were probably all due to vascular disease. The interest in the case was furthered by the fact that the other eye of the patient was removed for secondary glaucoma simulating an intraocular growth, and on examination it proved to be a case of extensive subretinal exudation, with retinal detachment and an old organizing haemorrhage, but no growth. The patient's sister also lost an eye from a similar cause, and the same condition was found on pathological examination.

A Filament in the Anterior Chamber.

Dr. GEORGE MACKAY reported a case in which an epithelial filament resembling a threadworm was observed in the anterior chamber of the eye of a girl aged 7. The child had always enjoyed good health, had no special illness, had never suffered from worms, and had not complained much about the eye. The filament had been first noticed when she was 8 months old. No independent movement had ever been detected in it, but the parents were under

the impression that it was slowly increasing in size. The eye was occasionally a little irritable, with a tendency to lachrymation, and a trace of ciliary injection. The tension was normal, the media otherwise transparent, and the fundus healthy. The pupil responded to light, although it was less mobile below than above. At the periphery of the iris, close to the anterior chamber angle, between the 5 and 6 o'clock meridians, a buffy-grey filament about a millimetre in diameter emerged between the fibres of the iris, and lay in close relation to the posterior aspect of the cornea, and appeared to rest lightly in contact with the sphincter surface of the iris. The structure terminated in a slightly bulbous free extremity, which did not re-enter the iris, nor extend to the angle of the anterior chamber. The arched filament had thus a slight spiral twist from before backwards. The vision of the right eye was approximately $\frac{2}{5}$; the left, $\frac{5}{6}$. The child was put under chloroform, and through an incision made at the corneo-scleral junction a little to the nasal side of the filament the foreign body was successfully removed, though breaking into two pieces, on account of its brittle structure. From the pathological examination made by Dr. Shennan of Edinburgh and Mr. A. E. Shipley of Cambridge no confirmation was obtained of the presence of a parasite. Microscopic sections showed that the filament was mainly composed of stratified epithelium, with a little loose connective tissue and some melanine pigment.

International Notation.

Mr. W. H. H. JESSOP presented the report of the International Committee on the Unification of the Notation of Visual Acuity and of the Meridians of Astigmatism. The following were the conclusions: (1) The meridians of astigmatism should be measured and represented as the observer looked at the patient; (2) the axes should be measured and represented in the lower semicircle of the trial frame. The numbering of the axes should start from the middle line of the face in each eye, and proceed downwards and temporally. The zero would therefore lie at the nasal end of the semicircle, and 180° at the temporal end; 90° would be below and midway between these points. The committee also agreed that for international test type numbers should be used. Landolt's ring was also thought to be a suitable object. The unit of measure was an angle of 1 minute, and the figures were to be constructed on this unit. The types were to be constructed as regards size on arithmetical progression, and the standard distance at which they were to be seen should be 5 metres. The source of light was to be diffuse daylight, if possible, opposite the types, and not laterally.

ROYAL SOCIETY OF MEDICINE.

SURGICAL SECTION.

Tuesday, June 8th, 1909.

Mr. WARRINGTON HAWARD, President, in the Chair.

Benign Tumours in the Wall of the Stomach.

Mr. WALTER G. SPENCER, in a paper on benign tumours of the stomach wall, related the case of a woman, aged 46, first seen by Mr. Barling. She then had three tumours in the abdomen, all freely movable. Two of them were mobile in the horizontal plane only, and these were taken to be the kidneys. Not until the operation was it ascertained that the third reniform tumour was really a submucous fibroma of the stomach. The tumour was shelled out and the patient did very well, resuming her occupation in three or four months. Two other cases of similar tumours from the Westminster Hospital Museum were exhibited, and reference was made to a number of reported cases. In the museum of the Royal College of Surgeons there were specimens of such growths from the horse and codfish. Diagnosis, except at the time of operation, was impossible, but it was important to remember that these neoplasms could easily be enucleated, and that it was unnecessary to excise any part of the gastric wall. Mr. BIDWELL drew attention to the fact that stomach tumours might be mistaken for mobile kidneys, and asked if the view that these innocent growths might "become malignant," suggested by the author, was generally accepted. Dr. MACNAUGHTON JONES said that myofibromata of the uterus certainly underwent malignant degeneration.

tion. Mr. HAWARD spoke of the invasion of benign tumours by malignant growth. Mr. SPENCKE, in reply, differentiated between surgical and histological malignancy, and spoke of the existence in the sections of his specimen of cells open to suspicion of malignancy, although the gross tumour was encapsuled and benign.

Gastric Surgery.

Mr. STANMORE BISHOP read a paper on some fifty cases of gastric operations, chiefly gastro-enterostomies, giving details of a number of representative examples. He laid stress on the value of x rays of the bismuthized stomach and intestines, both in diagnosis and in the study of the mechanical conditions existing after anastomosis. He also showed a series of clamps, some of which were of his own design, and intended to facilitate partial or complete gastrectomy. Mr. BIRWELL said that he never used clamps for his gastric operations, and pointed out the advantage of performing the anastomosis first, in the course of a partial gastrectomy. He had had experience of double gastro-enterostomy for hour-glass stomach, a procedure of which Mr. Bishop did not approve, and thought it could be performed with safety. In duodenal ulcer it was important to occlude the pylorus as well as to short-circuit the stomach. Mr. CHILDS mentioned a successful case of double gastro-enterostomy for hour-glass stomach. He advocated the performance of an anastomosis at the time of operation for perforation of a gastric ulcer, and illustrated the importance of early operation in these cases by instances from his practice. Mr. SPENCKE spoke of the desirability of having more than one type of clamp, a powerful one to crush the tissues and a thin-bladed pair for use subsequently, when applying sutures. Mr. BISROP, in his reply, objected to the attempt to occlude the pylorus, believing that it was impossible to secure permanent closure unless pylorotomy was performed.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At a meeting on June 4th Mr. CANNY RYALL, in opening a discussion on *Spinal analgesia*, stated that he now used it for operations on all parts, his list including craniectomies, excision of the sympathetic, extirpation of the larynx, and excision of one-half of the tongue, together with removal of the glands from both sides of the neck. One of his patients was a little girl 2½ years of age, who was submitted to an operation on the head without the slightest alteration in her general condition. He introduced the method of making high injections in Budapest and Vienna. In Vienna he injected an old woman from whom Professor Eiselsberg removed the greater part of her thyroid, weighing over 12 oz., with the greatest success. These results were due to Jonnesco's discovery, which enabled him to incorporate strychnine with novocain. Novocain was a depressant to the vital centres. Strychnine, on the other hand, was a stimulant. When these drugs were mixed together and injected into the subarachnoid space the strychnine, by neutralizing the depressing effect of novocain, prevented the occurrence of respiratory paralysis. For operations on the upper part of the body he inserted the needle into the first, and for operations on the lower half into either the eleventh or twelfth dorsal spaces. He rarely used lumbar puncture, since better results were obtained by making injections into the dorsal region. There was no advantage in making a cervical puncture, for perfect analgesia lasting an hour or longer could be obtained in the head and neck by injecting the solution between the first and second dorsal spines. The great danger of spinal analgesia was the likelihood of respiratory paralysis supervening; but now that it was known that strychnine prevented its occurrence, it should be the duty of every one employing this method to incorporate this drug with the analgesic solution.

NORTH OF ENGLAND OBSTETRICAL AND GYNAECOLOGICAL SOCIETY.—At a meeting in Leeds on May 21st, Dr. J. W. MARTIN (Sheffield), President, in the chair, the following were among the exhibits: Dr. E. O. CROFT (Leeds): (1) The left kidney from a fatal case of *Pyelitis in pregnancy*. The patient died in coma a few hours after a series of three fits. She was six months advanced in her second pregnancy. The first pregnancy occurred six

years before, and the labour had been followed by convulsions. The kidney was hydronephrotic, and contained a large quantity of milk like pus. The dilated and thickened ureter contained caseous material. The right kidney was normal in size, and on naked-eye section showed evidence of slight fatty degeneration; its capsule stripped easily. (2) A large, solid *Broad Ligament tumour* of unusual character. It had been enucleated from the broad ligament of a woman of 47 years without injuring the corresponding tube and ovary. It weighed 14½ lb., and measured 10 to 12 in. in various diameters. On section it showed a central, well defined, oval mass, 5 or 6 in. in diameter, of the consistency of a soft uterine fibroid and of a light brick-red colour. This was surrounded by a broad band of material of a myxomatous appearance. From this area a considerable amount of fluid exuded. The tumour was apparently an oedematous fibroid which had undergone central "red degeneration" and myxomatous degeneration of the peripheral portion. Dr. CARLTON OLDFIELD (Leeds): A specimen of *Carcinoma of the cervix* which had been removed by Wertheim's method. The patient was only 30 years of age. She was also suffering from syphilitic rubra and ecthyma. One enlarged lymphatic gland was found in the parametrium close to the cervix. Mrs. OXFORD (Pontefract): A specimen of *One-eyed monster* (cyclocephalus). Dr. J. B. HELLIER read the notes of a case of *Double uterus and vagina with unilateral haematocolpos*. The patient, aged 16, had menstruated regularly and normally for two years, with a little dysmenorrhoea. For some months she had noticed a swelling at the vulva but only at the monthly periods. Retention of urine led her to seek advice. There was a normal vaginal passage leading to a normal cervix uteri on the left side. On the right was a cystic swelling occupying the whole length of the vaginal wall, and protruding from the vulva. On incising this about 6 oz. of dark red inspissated menstrual fluid escaped. The right half of the uterus was also dilated but there was no sign of a haematosalpinx. The vaginal septum was completely excised. The patient had menstruated normally since. Dr. Hellier also showed a *Uterus with double pyosalpinx*. The uterine body had been amputated because both tubes and ovaries had to be removed. There was a septum extending to the os externum, and completely dividing the uterus into two cavities.

Reviews.

THERAPEUTICS.

Dr. I. LIPOWSKI, in the preface of his book on the value of the more important new drugs, says truly that to estimate the therapeutic value of new drugs put forward by able researchers, or as commercial speculations, is a hard task for the doctor. The volume is an attempt to place the new chemical drugs on a plain basis in the mind of the practitioner who, the author wisely assumes, has forgotten the chemistry he learnt as a student. Dr. Lipowski does not pretend to deal with all the vaunted synthetic remedies, but only with those proved in his own experience, or attested by reliable authorities. The drugs discussed are classified on the whole according to their chemical composition, but where such an arrangement would be inconvenient the author has wisely dropped it. Thus, in addition to sections dealing with the derivatives of methane, benzene, and the alkaloids, there are sections on antiseptics, new purgatives and diuretics, preparations of organs, serums, and new foods. Most of the important drugs recently introduced are mentioned, and discussed clearly but thoroughly. The short section on new purgatives treats of purgatin or purgatol, exodin, and purgen. It is shown how anthraquinone is related to anthracene, the active principle of rhubarb, cascara, and other purgatives; the trioxanthraquinone works so strongly in the intestine that colic is caused. The problem was, therefore, to combine this substance in such a way that it would be set free gradually in the intestine and a moderate but efficient stimulation obtained. Such a combination was found in the diacetyl-trioxanthraquinone or purgatol. Of the new diuretics

¹ *Abhandlung zur Darstellung und Bewertung der wichtigsten neueren Arzneimittel*, I. Lipowski. Berlin: Julius Springer, 1908. (81 in. by 5½ in.; with an introduction by Professor Senator.)

of the xanthin class theocin is the most active, but it may stimulate the brain even to convulsions, and is irritating to the gastric mucous membrane; these serious disadvantages are avoided by using theocin sodium acetate, but it is best to give even this in the form of suppositories. Theobromine sodium salicylate or diuretin is recommended in heart failure, either combined with digitalis (pulv. fol. digit. gr. jss, diuretin gr. xv, three to five times a day) or after digitalis has ceased to produce diuresis. The sodium acetate salt of theobromine, agurin, has the advantage over diuretin that it upsets the digestion less; it should be given in rather smaller doses. The author does not speak well of the artificial digitalis preparations. Digitalin is, he says, usually digitoxin, and digitoxin, or digalen, is so poisonous that it is only recommended when a rapid action is imperative; the drug should then be injected into a muscle or a vein, as it is extremely irritating when put under the skin. On the whole Dr. Lipowski prefers the powder of digitalis leaves; when made from a large quantity of material and very carefully dried, this preparation will keep its strength for a long time, and should be standardized by its action on the frog's heart. The powder acts more slowly than the separated active principle, but in heart disease this is often an advantage. We can recommend this little treatise, and regret that we know of no equally informing and readable book of the kind in our own language. Between 200 and 300 drugs are discussed.

In a little volume on sleeping draughts by Dr. C. BACHMANN the composition, pharmacological action, and doses of all the more important hypnotics are carefully described under three main groupings—namely, those containing (1) halogen elements, (2) alkyl radicles, (3) aldehydes or ketones. The general and local anaesthetics, the anodynes, such as opium, and the sedatives, such as bromides, are not considered. Each drug is briefly, readably, and systematically discussed, the name of the manufacturer and, in many cases, the price being given. Of especial value are the sections upon the effects of the drugs other than the hypnotic effect. A short bibliography of each substance is also provided. The author speaks highly of bromural in cases in which no severe pain is present, and, so far as observations have been recorded at present, the drug seems to be free from undesirable after-effects than many others. It is, however, apt to fail in the most difficult cases. For mild cases of sleeplessness bedonal is recommended in doses of 20 to 30 grains, and is best given in cachets. It is claimed that there is no stage of excitation or fear of cumulative action, and little danger of the patient becoming accustomed to the drug, whilst unpleasant secondary effects are rare. Veronal is treated at some length, as befits its wide use, and is described as a relatively harmless and reliable hypnotic, particularly in neurasthenia, senile dementia, mania, melancholia, paranoia, delirium tremens, hysterical sleeplessness, alcoholism, and morphinism. It may also replace morphine in the cough of phthisis. One disadvantage is the varying time which expires between the administration of veronal and the production of its effect. It may be tried in valvular disease of the heart, and does not irritate the kidneys. Apart from its action as a sleeping draught, veronal has been found useful in the night sweats of phthisis; indeed one author places it before both agaricin and atropine in this respect. It is also recommended in the hyperemesis of pregnancy, in epilepsy and multiple sclerosis, and as a prophylactic against sea sickness. The bad effects which have been observed are nausea and various rashes, headaches, giddiness, and even coma. Women appear to bear veronal, like sulphonal, rather worse than men. A number of instances of the formation of a veronal habit are recorded, and the doctor is advised never to prescribe more than six to ten powders of half a gram ($\frac{1}{2}$ grains) at once, and to write on the prescription "*Ne reiteretur.*"

Dr. TYRODE'S *Pharmacology* purports to "give the facts essential to an ordinary medical student without profound

scientific discussions of opposite opinions," and the reader will not, therefore, be surprised that it is throughout dogmatic rather than judicial. The style suggests that the author has published his lecture notes with but little expansion. Here and there are expressions that we could wish improved upon in a subsequent edition; particularly might the free use of superlatives be modified with advantage, and exacter terms than "infinitely more marked," "terrible," and "tremendous" would carry greater weight with the reader. The student will find a concise and up-to-date account of the actions of the more important drugs, but such matters as the general modes of action of drugs, idiosyncrasy, tolerance, and the growing and important subject of the relation between the chemical structure and physiological action of medicines, are inadequately treated; so that we fear we cannot recommend the volume to those reading for examinations in pharmacology in this country. For the practitioner who needs a book which will give him in some detail the action of any particular drug he may be desiring to use the information is too scanty, for some important drugs, such as strophanthus, receive only the briefest mention.

The structure and properties of the colloids are likely to occupy the attention of scientific men for an indefinite future period, since living tissue is colloidal. To the chemist, the biologist, the bacteriologist, and the physician, the study of these is of great importance, but is only just beginning to be intelligible. The term "colloid" has been extended beyond the limits in which it was used by Graham, for there are many substances not ordinarily known as colloids which do, under certain circumstances, form colloidal solutions, or solutions which are physically comparable to very fine emulsions—a state between the liquid and the solid—the substance being in molecular aggregates too small to be seen by the ordinary microscope. Dr. STODEL, in his recent book on the subject,⁴ first gives a general review, and then describes the methods by which colloidal solutions of metals, such as gold, silver, platinum, and mercury, may be produced. An interesting and readable account is given of the method of examining very fine particles by the ultra-microscope, and of the results of calculations of the actual size of the various colloidal particles; a discussion follows of adsorption, the movement of electrolytes, the action of electrolytes on colloids, and the action of colloids upon one another. A section on the colloids in biology treats of the various body fluids and of diastatic action, absorption, and immunity. The specific properties of the colloidal metals are then considered, and the inhibitory action of collargol upon bacterial growth, and its action upon the tissues when it is injected into the veins of an animal, described. The section on the treatment of disease by metallic colloids is less satisfactory, as the proof that these substances, in virtue of their catalytic and bacterio-inhibitory powers, exercise any definite effect upon morbid processes is naturally difficult to obtain. From the figures given it appears that, with medication of this type, the fatal diseases continue to be fatal, and the recoveries in the complaints amenable to treatment do not seem to be more frequent than is the case with the means, based upon a more secure pharmacological foundation, which we have at our disposal. The matter is capable of experimental proof, and we prefer to withhold judgement until a much larger number of observations upon infected animals has been made. The last part of the volume is occupied by a discussion of colloid mercury, electrically prepared. Dr. Stodel gives bacteriological experiments which lead him to conclude that colloidal mercury is more active as a germicide than the perchloride and is less toxic to rabbits. The electric colloidal preparation in isotonic solution is also not haemolytic for the red corpuscles of the dog. Therapeutic doses injected into the veins or muscles of man produce leucocytosis in twenty-four hours. The use of colloidal mercury, electrically prepared, in syphilis is illustrated by 59 cases of the primary, secondary, and tertiary disease. The author states that the intramuscular injection is painless and rarely gives rise to local reaction. Intravenously, large and repeated doses may be used without giving rise

to toxic symptoms. Intraspinal injections are followed by a temporary meningeal reaction only. Solutions containing 0.5 and 1 gram per mille were used. Three c.c.m. of the weaker solution may be injected into the muscles daily. In severe cases 5 to 10 c.c.m. may be injected daily into a vein. The intraspinal injections of 3 c.c.m. were used once a week and of the stronger solution 2 or 3 c.c.m. may be given intramuscularly.

In this volume Dr. v. WALDHEIM⁵ discusses the elimination of poisonous material by the skin, the promotion of which he describes as an effective method of treatment of all forms of fever. The book is intended to show whether the old view that the excretion from the skin in health and disease contains important poisons the retention of which will injure the body, or the modern teaching that it consists merely of water, carbonic acid, urea, salt, and minute quantities of fatty acids which are of little significance, is correct. The author does not appear to doubt that every one is definitely for one or other of these propositions. He himself is perfectly clear, and believes that modern medicine has wandered in error on this matter for the past eighty years, and that thereby enormous harm has been done to mankind, to science, and to the medical profession. The first sixty-nine pages are occupied with a review of the older teachings as to the nature and treatment of fevers, from the time of Hippocrates to the present day; the next forty pages treat of the work of Jäger and Lahmann. The author then describes very briefly his own experience, telling how he has cured himself of phthisis more than once, including attacks of rhinitis, angina, pharyngitis, tracheo-bronchitis, laryngitis (on one occasion with perichondritis), and influenza, by the Jäger-Lahmann process of wet packs, massage, and a dry diet. Then follows a long list of the diseases to be treated by this method. Aural surgeons will be interested to know that mastoid inflammation as a complication of suppurative otitis media can be prevented with certainty. Dr. v. Waldheim details the various fatty acids passed out in the sweat, which are in such small quantities that they are recognized chiefly by their odour, and concludes that the benefit which experience shows to follow a free perspiration is due to the removal of substances exerting a harmful influence on the organs of the body, particularly the brain. On the statement that a nerve is more irritable when it contains less water—which we may remark is only true within very small limits—he concludes that the beneficial result of sweating is partly due to the withdrawal of water. The compensating effect of more or less secretion of urine is not mentioned at this part of the argument. Bacteria, also, are said to be passed out, and hence free perspiration lessens the number of these in the body. No more need be said to show that the book is one of those not uncommon productions of an enthusiast bent, though probably all unconsciously, on riding his hobby to death. Anything that any one has written which seems to support the views of the author is dragged into the argument. The dietetic and balneological measures advocated are in themselves useful weapons in the therapeutic armoury, but, when applied and advocated with lack of judgement, an important branch of medical work is brought into disrepute. In spite of the proverb, it is possible to have a great deal too much of a good thing. Of bad things, such as hasty conclusions and analogies masquerading as proofs, a very little is too much, and 166 pages insupportable.

In a reprint of a paper in the *Deutsche monatschrift für Zahnheilkunde*, Dr. C. RÖSE⁶ begins with an introduction in which he says that when clinical observation shows that certain degenerations are becoming more and more evident in areas deficient in particular saline constituents of the food and drink, we may conclude that the want of the salt or salts is the cause of the degeneration. Such a process of reasoning does not lead us to hope for real accuracy of thought in the rest of the book. There is, however, a valuable series of statistics gathered from various regions in which the hardness of the water is com-

pared with the incidence of diseased teeth, and accompanied by exhaustive discussions of their meaning. The following conclusions may be mentioned: The harder the water the less the incidence of dental disease and of rickets, and the greater the quantity and alkalinity of the saliva. On a similar statistical comparison the author concludes that certain districts in which military ability is least marked owe this distinction to the fact that the drinking water is poor in calcium and magnesium. "Lime-poor" stock is a bad recruiting material. It follows that it is of the greatest importance, if we wish to be able to bite our food and to annihilate our enemies, that none of the salts in the food should be wasted. To this end, vegetables should be steamed and not boiled. We find ourselves in full agreement with the author's conclusion that the best cure for the evils attributed by him to lime starvation (and incidentally for most others) is that advised by Goethe—

Leb mit dem Vieh als Vieh
Und achte es nicht für Raub
Denn Acker, den du pflanzt, selbst zu düngen,
Das ist das beste Mittel, glaub,
Auf achtzig Jahr dich zu verjüngen.

DR. FERDINAND HUEPPE⁷ in a monograph upon chicory, after reviewing the literature of the subject, which is mostly hostile, points out that the harmful effects of an excess of coffee are to be ascribed to the caffeine it contains, and that the addition of some other material which does not contain caffeine is, therefore, desirable. Chicory when roasted provides a bitter taste, contains volatile oils, and gives a dark colouring to its infusions. Analyses are given of chicory from seven different regions of the Continent. The bitter taste is said to be derived from the cooking of inulin, and the dark colour from inulin and sugar. Beyond the statement that there is insufficient reason to believe that chicory is harmful, no evidence is brought forward to show whether it has any specific effects or not. The author in the early pages proposes to investigate the matter, but reaches the end of the pamphlet without describing any new pharmacological experiments.

PARCIMONY IN NUTRITION.

WHEN a Lord Chancellor's Visitor in Lunacy intervenes into a controversy on dietetics one is inclined to say, Que diable allait-il faire dans cette galère? But Sir James Crichton-Browne is, if not omniscient, a very able advocate who can get up his brief admirably. His book, *Parcimony in Nutrition*,⁸ is founded on a popular lecture delivered at Buxton last year, revised and enlarged. It is superfluous to say that it contains much that is wise and well expressed, but he throws all the weight of his influence on the side of those liberal feeders who after middle life come so surely into the hands of the physician. It is true that he says "there is far too much adipose tissue about in certain social strata," and he admits that some people eat too much, but his general line of argument is that a full and generous diet, especially in the allowance of proteid food, is the basis for individual and racial superiority. He makes many doubtful statements—for example, that "the whole population of all civilized countries" (p. 7) uses an ample diet, especially of proteids; that this diet has been founded upon "statistical and experimental studies" (p. 7), although elsewhere (p. 22) he admits that "the science of dietetics is based on common observation and on the hereditary customs and habits of mankind"; that "all the successful races have habitually consumed proteid far in excess of the Chittenden standard," although the Greeks and Romans were largely vegetarian in their diet, and we have no data upon which we can estimate the proportion of proteid consumed by them; that "the best fed races and classes are always the best tempered," a statement which, so far as classes in England are concerned, will not, we suspect, generally be accepted; while, as to races, the West African negroes and the Irish are generally admitted to be the most good-tempered people although among the worst fed; the well-known case, too, of the bear quoted by Liebig directly

⁸ *Parcimony in Nutrition*. By Sir James Crichton-Browne, M.D., LL.D., F.R.S. London and New York: Funk and Wagnells Company, 1909. (Cr. 8vo, pp. 118. 3s.)

contradicts Sir James's theory. Again, he says: "In all civilized countries the working classes have as far as practicable arrived at a tolerably uniform diet," which is very far from accurate, as workmen in England, America, France, Germany, Spain, and Italy do not eat a "tolerably uniform diet." Moreover, while he has a perfect right to criticize Chittenden's conclusions, he need not create prejudice by mixing them up with many foolish statements from writers on quite a different plane, like Fletcher, Carrington, Dewey, Kellogg, and other members of the great army of faddists. When he quotes Mr. Rowntree as saying that a large proportion of our population is underfed he ought to have added that Mr. Rowntree based this conclusion on the assumption that Voit and Atwater's standard of proteid dietary was universally accepted. Sir James claims that civilization is "not the antithesis of nature but a higher branch of natural history." We take him to mean by this that the habits and customs of civilization are the results of natural evolution, and that consequently the dietary which civilized men have adopted can be regarded as a conclusion arrived at on the principle of the survival of the fittest. This was a principle the late Sir William Roberts was fond of enunciating, and though it contains an element of truth, it ought to be applied with discrimination; it may equally be argued that so far as man's physical development is concerned, civilization has been a continued struggle against evolution, and consequently contains in itself the seeds of failure and decay. Horsekeepers tell us that the full diet given to the fine animals we see drawing railway wagons enables them to do a large amount of work, but their lives are short; so, too, with man it is probable that a full diet containing much proteid enables him to do a maximum amount of work, but it by no means follows that it is favourable to his continued health or to his prospects of longevity. We may be quite prepared to allow that Chittenden's conclusions require confirmation, and that this can only be obtained by further experiments and observations, and we may agree fully with Sir James Crichton-Browne that during the growing age a liberal supply of proteid is necessary, without sympathizing with his rhetorical attack on Chittenden and those who believe with him that economy in nutrition may be obtained on a diet which, while considerably below the Voit and Atwater standard, sufficiently maintains health and strength and does not cause the development of those disorders of metabolism which are unquestionably associated with overfeeding. It is probably true that in England gross and excessive indulgence in food is by no means so common amongst the educated classes as it was a hundred years ago, but it is still seen in all ranks, and the belief in the need for large quantities of food is widespread; it is also true that a small minority of faddists go to the other extreme and eat too little; but while the physician is well acquainted with the diseases resulting from excessive eating, he has as yet learnt comparatively little about those depending upon under-feeding, except where morbid conditions interfere with the normal desire for food.

FACE MASSAGE.

The treatment of morbid cutaneous conditions of the face by means of massage has been somewhat neglected, owing to the impudent quackery associated with face massage. But there is no doubt that the method is valuable in such diseases as acne vulgaris, acne rosacea, and so forth, in combination with rational general treatment of each individual case on its merits. Dr. Jacquet has recently called attention once more to the beneficial results obtained by pinching up the skin of the face, followed by superficial *pétri sage*, a method he calls "plastic massage." One of his pupils, Dr. Leroy, who has employed this method, has written an instructive monograph on the subject,⁹ in which the various modes of using massage are compared with the method suggested by Dr. Jacquet. A *sine qua non* is that the hands must be kept scrupulously clean. No ointments are used, but a powder (kaolin, talc, etc.), in order to give a purchase on the parts. A strong yet delicate male hand is required to apply the proper amount of pressure requisite in each case, com-

mencing lightly, and gradually increasing in vigour. As before stated, general treatment is important—in acne cases, for instance. Suggestions are made as to where mastication, vegetarianism, attention to the teeth, bowels, etc., are indicated. Details of 25 cases are given, in which the facial manifestations were associated with a variety of etiological factors. Dr. Leroy's work will well repay perusal by any one desirous of giving the method a trial.

NOTES ON BOOKS.

THE transactions of the International Society of Surgery at its meeting in Brussels last year have been published in two volumes, entitled *Deuxième Congrès de la Société Internationale de Chirurgie, Bruxelles, 21-25 Septembre, 1908. Vol. I, Procès-verbaux et Discussions, et vol. II, Rapports*.¹⁰ The proceedings were reported in our columns at the time, but surgeons all over the world will be glad to have the full text of the papers and of the discussions, for this society is in a way unique. It is an extremely business-like society; its members are limited in number, since only those surgeons invited by the international committee can become members, or attend its meetings; and, judging by the proceedings of the two meetings which have been held, it intends to devote itself to the discussion of practical matters directly concerning operating surgeons actively engaged in that department of professional activity. The volumes have been edited by the Secretary-General (Dr. A. Depage) and the Secretary of the congress (Dr. L. Mayer), and have been very well and clearly printed by the Royal Printing House in Brussels. The way in which the volumes have been prepared for the press and their relatively early publication reflect the greatest credit upon the two editors, and the only criticism we feel called upon to make is that the photographs are not so well reproduced as desirable. The papers are published in the official languages, English, French, German, or Italian, according to the nationality of the author, and the volumes will form an indispensable part of every reference medical library.

The latest fascicule of the *Archives of the Middlessex Hospital*¹¹ marks a new departure and bears a subtitle, "Clinical Series No. 1." It contains some half-dozen papers, mainly of a clinical order, and the reports of the medical, surgical, and obstetric registrars for the year 1907. In future there will be four issues yearly, one of them dealing with the cancer laboratory and the connected work, and the other illustrating the teaching of the hospital in respect of the latest developments of medicine and surgery.

MR. WALKER-TISDALE's little book on *Milk Testing*¹² is intended to give farmers, dairymen, and milk consumers information with regard to simple tests for ascertaining the purity and quality of milk. Thorough knowledge of the subject is shown by the author, and the book should prove useful within the limits of its purpose. It is probable, however, that a farmer or dairymen who was willing to go to the trouble and expense of providing the apparatus, etc., described would find it better to make an arrangement with a competent chemist for the systematic checking of his milk. The danger in imparting a little knowledge is illustrated by such a statement as "annatto colouring is of a harmless character, owing to its being of vegetable origin," no caution being expressed against the natural inference that any substance of vegetable origin must be harmless.

The volume entitled *Studies from the Department of Pathology of the College of Physicians and Surgeons of Columbia University* is the eleventh of a useful series. Most of the papers contained in it have appeared in some one or other journal during the past two years, but their collection in this form makes reference to them easier than it otherwise would be. Included is an elaborate paper by Drs. Bovaird and Nicoll dealing with the weight of the viscera in infancy and childhood. The average weight of 495 thymus glands of children of all ages from birth up to 5 years old was 5.9 grams. The extremes were 4.6 grams for the second month, and 7.7 grams at birth. The cases were unselected, and represented the result of all autopsies at the Foundling Hospital during a period of about three years.

¹⁰ Bruxelles: Hayez, Roy, 8vo; vol. I, 528 pp.; vol. II, 916 pp.

¹¹ Macmillan and Co., 10, 102.

¹² *Milk Testing: A Simple Practical Handbook for Dairy Farmers, Estate Agents, Creamery Managers, Milk Distributors, and Consumers.* By C. W. Walker-Tisdale, F.C.S., N.D.D. Northampton: W. R. Smithson, 1908. (Ct. 8vo, pp. 78, 1s.)

⁹ *Le massage plastique dans les dermatoses de la face.* Par le Dr. Raoul Leroy. Paris: Alex. Coqueux, 1908. (Roy. 8vo, pp. 193; 11 illustrations. Fr. 4.)

In *The Mystery of Existence*¹⁸ Mr. A. C. W. ARMSTRONG essays the task of making metaphysical theories fit in with established beliefs. Even though—for him—conscious being is merely an incidental, if not accidental, exhibition of the subliminal self, which is an intrinsic part of the general World-spirit, individually exists and is growing. So, too, does free will, while love is a necessity and the aim of the whole World-spirit. Similarly, although matter is merely the concrete idea or conviction of the World-spirit, it is perfectly real. There is a God whose powers are only finite in that they are regulated by the Laws of Nature, which are the Law of Thought, this in its turn being the Law of Mathematical Possibility. If there are any persons who have studied metaphysics sufficiently deeply to follow the writer's arguments and understand his terms, but not deeply enough to have learnt to keep working beliefs and metaphysical conceptions comfortably packed away where they can do one another no harm, this book will probably meet their case. Its direct interest for medical men is the view of the author that predominance of a belief in immortality retards the progress of hygiene. Continuance in this world being a matter of secondary importance, attempts to prolong life have hitherto been insufficiently resolute. Some day or other the span of normal terrestrial existence will be so long that original thought or research will be expected of no one under the age of 70. Over-population of the globe will then be prevented by restriction of the right to propagate species.

THE SEVENTH INTERNATIONAL CONGRESS OF APPLIED CHEMISTRY.

THE SECTIONS.

Lipoids and Pharmacological Action.

Dr. HANS MEYER, speaking in German before the Section of Physiological Chemistry, read a very able paper on the relations between lipoids and pharmacological action. He stated the evidence in favour of the theory that the animal and vegetable cell protoplasm practically consist of minute albuminoid particles encompassed by layers of lipoids, which take up water, salts, and fat solvents. This lipoid prevents the hydrophilic colloids, enzymes, albuminates, etc., from diffusing out of the cell at random or from acting on each other. It further allows of the taking up of oxygen and carbonic acid. The carbon dioxide in the blood cell renders the cell permeable to sugar and anions, and in a similar manner the fat solvents act on the lipoid of other cells, rendering the intake of water, salts, and other substances possible. Turning to the phenomenon of hæmolytic, he described the various degrees of solution of lipoid content of blood cells, and applied a similar argument to other forms of cytotoxicity. Narcosis and anaesthesia could be understood from a study of the lipoids; heat partially liquefied these fat-like substances, and the unconsciousness of fever was due to a heat change in the lipoids of the brain cells. Experimentally this would be demonstrated by placing a frog or other cold-blooded animal in warm water. Water at 38° C. caused anaesthesia in the frog in a few minutes, but it could readily be awakened by immersion in cold water. Anaesthesia by heat in warm-blooded animals was not safe, because the lipoids were not affected until the temperature was near that which coagulated proteins. Fat-dissolving gases, however—such as ether and chloroform—could effect a safe partial solution of the lipoid of the brain cells. As soon as they were removed the lipoids returned to their original condition and the person awakened. The narcotics acted in a similar manner, and the narcotic power of a drug depended on its lipid-dissolving power. The actual pharmacological action was measured by the smallest molecular concentration of the substance which would put small fish to sleep when immersed. He had found that the "distribution coefficient" obtained by dividing the solubility of the substance in fatty substances by the solubility in water stood in direct relation to the pharmacological action. A table of narcotics, including trional, tetronal, etc., showed this relation clearly. Narcosis was thus a change in the physical condition of the lipoid, and this change involved a corresponding change of the normal permeability of ions of the cells. On this theory irritability of cell and

pharmacological action could, he contended, be adequately explained.

Professor B. MOORE, who spoke next, dealt with the chemistry of the unsaturated fatty acids. Basing his opinion on the evidence obtained by his own researches and those of other workers, he came to the conclusion that lipoids were not independent chemical substances, but part and parcel of the large cellular molecule, which consisted of carbohydrates, proteins, and these fatty substances. In substance he agreed with much that Dr. Meyer had said. He believed that some narcotics—for example, cocaine—do not owe their action to their fat-dissolving power.

Dr. NICLOUS supported Dr. Meyer's theory of the function of the lipoids. He had conducted experiments with Mlle. Frison which demonstrated that the various portions of the central nervous system of an animal killed by prolonged chloroform intoxication took up chloroform in direct proportion to the amount of lipid or lecithin of that particular part.

Dr. BARBIERI failed to convince the majority of those present that lecithin does not exist. Part of his communication dealt with the analysis of the yolk of eggs, while the second part dealt with the chemical constitution of the nervous system.

In reply to Professor B. Moore's objection to the assumption of a separate entity called lipid, Dr. MEYER pointed out that the only difference between them was that he believed that the lipid surrounded the protoplasmic particles as a membrane, while Professor Moore regarded it as a part of the protoplasmic molecule.

In this connexion Dr. ROSENHEIM read a paper proposing a recasting of the nomenclature of the lipoids. The ideas expressed, although based on rational grounds, did not meet with much support.

Control of Food Supplies.

In opening the discussion on the systems in force for the control of the food supply, Dr. WILEY made a very long communication, which in substance consisted of: (1) A description of the American laws placing a tax upon food products, and of the laws controlling interstate and foreign commerce; and (2) the methods employed in the several States of America for detecting adulteration and misbranding, and for punishing the persons offering such foodstuffs for sale. Tea, spirits, wines, cheese, mixed flour, oleo-margarine, and butter were, he said, subjects of special legislation. The sale of meat was controlled by a Meat Inspection Act, and the misbranding of food and dairy products had been rendered a punishable offence; the Food and Drugs Act of 1906 dealt with adulteration and misbranding. The State and municipal laws affecting food control were administered by the Secretary of Agriculture and the Bureau of Chemistry centrally and by State officials locally. When the foodstuffs were liable to duties or taxes, the Treasury Department in the Bureau of Internal Revenue had the execution of the provisions. The method of taking samples for analysis was described; it consisted usually in taking three samples, each of which was sealed by the inspector. The method of taking action against offenders varied in the different States. The penalty was either a fine or imprisonment, or both. Imprisonment was usually reserved for a repetition of the offence. There were special arrangements for the control of imported goods, and when an analysis disclosed misbranding or adulteration, the goods had either to be relabelled or exported beyond the jurisdiction of the United States.

Dr. ROUX, the chief of the French Service, described the law of 1905, which dealt with commercial and sanitary frauds, but did not touch fiscal frauds. The Act was amplified by a number of supplementary laws. Frauds and falsification are determined by the ordinary methods, and the law deals with ordinary foods, liquors, grains, fodder, etc. Inspection was carried out by agents of each prefecture. Four samples for analysis had to be taken, one of which was sent to be analysed in the first instance, while the remaining three were reserved for a second official analysis, and for analyses by an expert of the Court and by another selected by the accused. There were thirty-seven administrative laboratories in which such analyses were carried out. The practical effect of this law was a diminution of misbranding from 26.2 per cent. of the analysed samples to 12.6 per cent. Dr. BORDAS

gave an account of the work of the laboratories of the French Financial Minister.

Dr. BUCHANAN spoke of the administrative methods of food control in Great Britain and Ireland. He passed in review the workings of the Public Health Acts, the Weights and Measures Acts, the Merchandise Marks Acts, and the Sale of Food and Drugs Acts. He dealt in some detail with the sampling officers and their duties, the work of the public analysts, the offences and prosecutions for contravention and on the general question of proper descriptions of food stuffs.

Drs. WANTERS and KERF spoke of the regulations in force in Belgium and Germany. They were followed by Dr. McGILL who dealt with the control in Canada. He reported that the laws relating to the subject included: (1) The Adulteration Act, (2) the Inspection and Sale Act, (3) the Meat and Canned Food Act, and (4) the Canned Goods Act. The first of these acts was administered by the Minister of Inland Revenue, his deputy and the analyst of the department, assisted by six analysts and five clerks at Ottawa, four district analysts in different cities and a staff of sixteen inspectors. In taking samples, one was always left with the vendor, one was sent to the main laboratory, and the third at times to the district analyst. Adulteration of foods consisted in reducing quality or strength by admixture, substituting inferior substance, abstraction of valuable constituent, imitation or false naming, use of diseased or putrid material, addition of poison, strength or purity below fixed standard, colouring or coating to conceal damage, and milk or butter from diseased animals. Adulteration of a character injurious to health involved a penalty not exceeding \$500 or six months' imprisonment, or both. A few articles of food were dealt with specially.

After Professor SCHAFER had spoken of the control in Switzerland, Dr. VAN RUN, in a very interesting paper, described in detail the Dutch method of butter control. He stated that, as the Director-General of Agriculture in Holland was a permanent official, and the present incumbent of this office an extremely energetic person, the control of dairy produce and meat had received very careful consideration. In order to safeguard the export trade and to guarantee the purity of inland supply the official certificate, including a certificate, label, mark, stamp, or other voucher, was the first guarantee recognized by the British Local Government Board. In the past adulteration of butter was common in Holland, and the first step was to introduce uniform methods of analysis. These methods were also adopted in England. The difficulty in setting up a standard of quality of butter was insurmountable, and for this reason the method included the registering of the components of each parcel of butter by an analysis of the sample of the parcel, taken at the dairy from which it issued. The director or inspector visited the dairy when advisable and took a sample. The analysis of the sample was registered and the butter of the yield made in the presence of the inspector was stamped with the official stamp. In this way the record of every yield of butter at any time of the year was registered, and it was easy to trace by means of the register the origin and destination of every parcel. If such a butter was exported to England and offered for sale, a sample of it could be taken for analysis. The number being known, it was essential that the analysis made in England should correspond within narrow limits to that registered in Holland, and to which the English officials had access. The method of stamping was described, and books of specimen labels were handed round for inspection.

In the discussion, Dr. McKERR pointed out that fraud might be practised by cutting off the upper layers of the butter, including the label, and adulterating the remainder. He also raised the question whether the labels could not be imitated. Dr. THORPE spoke in terms of high praise of the method which he had personally investigated in Holland for his department. He described the system as one which was as perfect as human ingenuity could devise. It had revolutionized the position of Dutch butter on the English market. In reply, Dr. VAN RUN said that although the removal of the upper layer was theoretically possible, it would not be difficult to detect such a fraud, and in practice it did not occur. The labels could not be imitated more easily than a bank note.

A few other papers dealing with other branches of the same theme concluded this important and interesting discussion.

Preservatives in Food.

The discussion on this subject was opened by Mr. CRIBB, who read a communication by Mr. Bevan, in which the author advocated the prohibition of all preservatives in foods. Dr. Thresh's paper, read by Dr. RIDEAL, argued against the indiscriminate use of preservatives, but adduced evidence to prove that preservatives in reasonable quantities had not been shown to be injurious, that in many cases their use was legitimate and of benefit to the community, and that only in certain cases was the use of chemical preservative unnecessary and undesirable. Dr. WILEY, on the other hand, maintained that under all conditions preservatives should be regarded as adulterants. A trace of copper sulphate in peas might not harm a robust person, but to many weakly persons and invalids such additions must be highly injurious. Preservatives were unnecessary, and he wished to see them swept away. In the discussion, it was urged, from a trade point of view, that preservatives were indispensable. Another member considered that the trade could get on very well with pasteurization, and tried to show that the addition was not even in the interest of the producer.

Standards for Foods and Drugs.

Dr. BECK opened a discussion on the advantages and disadvantages of legally binding standards of composition. He considered that the amount of water in butter had increased generally since the adoption of a legal standard, and in consequence the dry butters of the Colonies had virtually disappeared from the market. Standards for natural products or articles of simple manufacture were of very doubtful utility; a standard was futile in the case of mixtures, such as coffee and chicory, because quality was of much greater importance than quantity. The setting up of legally binding standards in respect of the use of preservatives, colouring matter, etc., in foods was essential.

M. WANTERS regarded a standard for foods as unfair to the producer, who could not continuously make analyses of natural products, but might at any time be prosecuted for variations in composition for which he could not morally be held responsible. If the limits of the standard were wide no good purpose could be served, while whether they were wide or narrow, they would prove to be the means of legalizing frauds in the hands of unscrupulous persons.

MESSRS. MOOR and PARTRIDGE considered the question not only from the standpoint of the public and the producers, but especially in the interest of the poor, who needed protection. The setting up of standards saved the producer from unfair competition and satisfied the administrators that uniformity would be secured. He suggested certain standards for aerated waters, baking powder, beer, and brandy. With regard to bread, he contended that not more than 40 per cent. of water should be allowed. The amount had been in certain cases as high as 58 per cent. He considered that the standard of 16 per cent. of water in butter was too high, and the fixing of the standard had done good in reducing the quantity from 22 per cent., or even 24 per cent., and he thought a standard of 2 per cent. of salt advisable. Cream cheeses should contain at least 40 per cent. of fat; other cheeses at least 30 per cent. Cheeses containing less than this quantity of fat should be described as having been prepared from skimmed milk. No standard existed with regard to condensed milk, and he suggested that it should contain at least 10 per cent. of fat. Hand-skimmed cream should contain 10 per cent. and artificially-separated cream at least 50 per cent. of fat. Infant foods were rarely, if ever, examined under the Food and Drugs Acts; they should contain no starches and no impurities. The standard of 3 per cent. of fat in milk was still low; it was fixed at 3.5 per cent. in other countries. It had, however, risen from 2.5 per cent. He considered that the public analyst in every district should publish the percentage of fats contained in the milks supplied by the different dealers, mentioning them by name. In this way the public would be able to discriminate between the qualities of the various milks offered for sale.

Dr. KERP discussed the arguments for and against the setting up of standards. He considered that it would be impossible to determine generally whether standards were advisable, but that each foodstuff must be dealt with separately.

Professor WYSMANN dealt with the difficulties of setting up standards for wines, etc., which would not only fix the composition but also indicate the origin. With regard to milk, he considered that a legal definition should be the secretion from the udder to which nothing had been added, from which nothing had been abstracted, and which contained at least 2.5 per cent. of fat.

Dr. WILBY reported that hundreds of standards had been fixed in the United States, and he expressed himself in favour of efficient standards.

Dr. BORDAS contended that it was essential to have the co-operation of the manufacturers in fixing standards. He advised a waiting policy until the White Cross Congress should come to a decision. Mr. GILES described the work of the White Cross Congress at Geneva last year, which had tentatively fixed some standards; in Paris this year the manufacturers would recommend certain alterations in these standards, and next year a congress would consider how far the alterations had affected the hygienic value of the original provisions. A final congress would correlate the divergent views.

Sewage Effluents.

A large number of papers dealing with the treatment of sewage and sewage effluents were read. M. ROLANTS dealt with colloidal organic matter in sewage and its treatment by dialysis, by precipitation, and by agitation with an inert powder. Dialysis was unsatisfactory, the clarification method of Fowler by a ferric salt in alkaline solution had disadvantages, and better results were obtainable by precipitation with calcium phosphate. Agitation with talc or kaoline and filtration yielded much better results.

Papers were read by Mr. JOHNSTON on physical and biolytic purification of sewage, by Mr. DIBBIN on aerobic treatment, by Mr. SCOTT MONCRIEFF and by Mr. STODDART on nitrification. Dr. GROSSMANN read a paper on sewage sludge disposal, in which he pointed out that sludge after filtration and pressing into cake contained about 50 per cent. of solid matter. In many places the time was approaching when no further land would be available for dumping, especially since modern hygiene had shown that this method of disposal was not only objectionable but against all economic principles. The fact that sludge clogged up the soil detracted from its utility as a fertilizer. This was due to the content of fatty matter—grease and soap. About 400,000 tons of soap were used every year in this country, and practically all this found its way into the sewage. This meant that sludge would contain at least 5 per cent. of fatty acids. The recovery of the fatty acids by means of solvents or by destructive distillation was costly in the large majority of instances. Recovery by non-destructive distillation required careful consideration. He had experimented in this direction, and had set up a plant at Oldham capable of recovering 60 per cent. of the total solids of sludge as saponifiable matter. Each ton of sludge had yielded 1.4 cwt. of crude grease which had a marketable value of 9s. 9½d. The residue containing soil, organic matter, nitrogen, potash, and phosphate, was found to be an excellent manure. The value of this per ton of pressed sludge would be at least 5s. 9d. Estimating the values at a low figure, this would yield 13s. 6½d. for each ton of sludge containing 50 per cent. of water. The cost of working up the sludge was 6s. 11½d., so that there was a margin of 6s. 7d. a ton. Illustrating the value of this, he stated that in a town of 100,000 inhabitants, the cost of working up the sludge would be £2,610, whilst the sum realized by the sale of the products obtained would be £5,078, leaving a margin of close on £2,500.

In dealing with the tests for effluents suggested by the Royal Commission on Sewage Disposal, Dr. RIDEAL and Mr. BURGESS contended that local authorities should only be required to purify sewage so far that natural agencies could deal efficiently with the effluent without causing a nuisance. The Commission regard de-aeration and presence of suspended matter as the cause of nuisance, but the authors considered that anaerobic micro-organisms played an important part, and were concomitant with

de-aeration. The Commission had fixed the limit of suspended matter allowable at 3 parts per 100,000, but the authors regard this as too generous, as such an amount would cause deposits in sluggish streams. Dr. Rideal criticized Dr. Adeney's apparatus, and claimed that his own modification was a better instrument, while his colorimetric method was most simple and convenient. Dr. ADENEY, replying, denied that the Commission had recommended the use of his apparatus for testing effluents. The object of these tests was to determine the aerability of the organic matter present. Dr. MACGOWAN, the chemist to the Commission, supported Dr. Adeney's arguments. Mr. SCOTT MONCRIEFF spoke in support of Dr. Rideal's arguments, while Mr. HALLIVELL questioned the advisability of these tests, and pleaded for the continued employment of the older chemical analyses. Mr. O'SHAUGHNESSY did not think that 3 parts in 100,000 a generous allowance for suspended matter in sewage effluent, and gave his opinion that gravimetric tests by means of centrifugation yielded better results than filtration.

Dr. FOWLER dealt with trade effluents. For tannery effluents clarification by simple subsidence was as a rule satisfactory, but mechanical filters might be required in some cases. Brewery or distillery effluents required special biological tanks and filters. Colouring matters in effluents did not constitute a dangerous element in sewage, but were frequently destroyed in biological filters. Alkaline sulphides should be treated with lime or coppers, dilute alkalis and acids should be neutralized, and other chemical products dealt with according to their action on fish life in varying concentrations. In conclusion he dealt with some aspects of the law relating to this subject. Dr. HAUPT spoke on the cost of the removal of some products of trade waste. Alkaline sulphides cost from 5 to 6 pfennigs per kilogram for removal. Dr. PURVIS considered that sulphuric acid was satisfactory for brewery effluents, and objected to the use of lime, which when discharged into rivers killed fish. Mr. COLEMAN challenged this statement. Professor KILASON dealt with the clearing of the outfall water from the sulphite cellulose factories in Sweden.

Sewage Pollution in Sea Water.

Drs. KENWOOD and KAY MENZIES discussed the requirements of a satisfactory test of pollution injurious to shell-fish, and sought to determine whether sea-water contamination constituted a danger to bathers. The presence of *B. coli communis* could not under ordinary circumstances be regarded as a safe indicator, since *B. typhosus* might persist long after *B. coli communis* had disappeared. They considered that the presence of oxidized nitrogen in sea water in the form of nitrites would indicate contamination, but its absence would not guarantee freedom from contamination. Free ammonia might be accepted as a valuable clue to contamination, while albuminoid ammonia was not so suitable as an index. Neither oxidizable organic matter nor dissolved oxygen nor phosphates could be relied on to disclose contamination of sea water.

Dr. ADENEY demonstrated the simpler form of his apparatus for measuring the rate of absorption of dissolved oxygen in polluted water. The system depended on the absorption of oxygen dissolved in distilled water, which he considered better than the dilution system. He emphasized the fact that the work was pioneering work, and should not be regarded as finished. It was necessary to obtain agreement as to the interpretation of results before the methods could be adopted for general use. The paper and demonstration was much applauded.

Drs. PURVIS, MACALISTER, and MINNETT read a paper in which they adduced evidence that the total number of micro-organisms diminished more rapidly in a mixture of sewage and sea water than in sewage alone; that denitrifying micro-organisms could live longer in a mixture in which potassium nitrate was present, and that nitrifying organisms did not appear in sewage or sewage and sea water at any time.

A very animated discussion took place. Dr. RIDEAL entered a general objection to taking ammonia as the indicator of pollution of sea water; he described the methods which he considered best, including the determination of chlorine as well as ammonia, the samples being taken at different states of the tide and from the

bottom. He discussed some points with regard to Dr. Adeney's apparatus. Mr. HARRISON EDDY regarded the measurement of natural processes preferable to chemical measurements. In Boston the sewage was carried out a considerable distance from the shore, where the mass of water acted sufficiently in diluting the sewage to prevent a nuisance. The whole question was financial rather than scientific. Mr. HALLIWELL discussed the technical difficulties connected with Dr. Adeney's method, the chief being the necessity of constant shaking. He considered the apparatus Dr. Adeney had first described excellent, but did not like the simplified modification which he had demonstrated. Mr. Blake, of Belfast, stated that no smell was noticed when sewage was thrown into the sea, provided that a sufficiency of oxygen was present. Mr. ANDERSON did not obtain satisfactory results with Dr. Adeney's second apparatus, and preferred the dilution method. Dr. DYCK thought that phosphate examination was more important than Drs. Kenwood and Menzies would have the members believe. Mr. O'SHAUGHNESSY considered that Dr. Adeney's method was preferable to the dilution method. Professor Lett was not present, but a paper was read by Dr. ADENEY, upholding the reader's views. The readers of the chief papers then replied, but did not bring forward any fresh ideas. On the whole, the objections raised to Drs. Kenwood and Menzies's paper, and to Dr. Adeney's communication were sufficiently met in the replies to gain a consensus of opinion. In his reply, Dr. PURVIS dealt in some detail with the methods of determining nitrates, which he considered required minute attention.

Lead Absorption.

Drs. GOADBY and GOODBODY read an interesting communication dealing with an investigation on experimental lead poisoning. Having described the methods adopted they stated that the compounds employed were white lead, "market pot," and litharge. The preparations were applied by inhalation, by feeding either alone or together with wine, and by injection. Cats were more rapidly poisoned by inhalation than by feeding. The dust entered the respiratory passages from which it was absorbed; lead sulphide could be demonstrated in the alveolar cells, in the perialveolar tissue and in the lymphatics after treatment of the tissues with H₂S. When alcohol in the form of cheap port was given simultaneously, the course of poisoning became acuter. Feeding even with large quantities produced very little toxic effect. Death by lead poisoning could be caused by the injection of lead acetate in doses of 0.05 gram per kilo body weight. In conclusion the authors described some experiments with lead compounds digested with gastric and intestinal ferments. The effect of gastric digestion on white lead was to cause a slight increase in the solubility of the lead compound.

In the discussion Sir J. CRICHTON-BROWNE questioned the correctness of the view that lead dust could be absorbed directly from the lung. Analogy had shown that carbon, tubercle bacilli, and other particles are not inspired directly into the lung, but gained an entrance from the gastro-intestinal channel through the lymphatics into the lung. Professor MOORE had experimented with heavy metals for a different purpose, and supported the view that the heavy metals were more poisonous when applied to a surface like the respiratory passages than when taken into the stomach. Mr. ARMIT was able to confirm the views of the authors that dust could be directly inhaled and absorbed from the respiratory passages. His work with the heavy metals, such as nickel, iron, and cobalt, had given very definite evidence that this occurred. He had found that the absorption was dependent on the relative size of the surface of the particles to be absorbed and of the absorbing surface. Even insoluble compounds such as sulphides of nickel, iron, and cobalt could be absorbed from the peritoneum, where the conditions were favourable. The conditions in the stomach were not favourable for the absorption of heavy metals. Dr. LEGGE spoke from the clinical point of view. He had always held the opinion that lead was absorbed from the stomach, but the experimental evidence adduced by the authors and by the last speaker must be taken into account. He regarded the question of the situation of absorption as of academic importance only, since the preventive measures must be the same in both cases. Sir THOMAS OLIVER sup-

ported the authors and considered the finding of lead sulphide in the lung as conclusive proof that the inhalation of dust into the respiratory channels had taken place. He spoke of the resistance against the toxic effect of lead. That the loss of weight in lead poisoning was not due to starvation was shown by the fact that, whereas an animal only died of starvation when it had lost two-thirds of its body weight, the animals in the authors' experiments only lost one-third of their weight. The authors replied.

Entertainments.

On Tuesday evening, June 1st, in spite of heavy rain, there was a large attendance at a reception by Sir William Ramsay, the President, and Sir Henry Roscoe at the Natural History Museum, South Kensington.

Excursion to Windsor Castle.

A message from His Majesty to the effect that the congressists were at liberty to visit the Castle having been received, a large number of members and their ladies set out for Paddington Station early in the afternoon of June 2nd. The visitors were delighted with all that was to be seen, both within the grey walls and without among the verdant surroundings of the Castle. An exceptionally fine view was obtained of the surrounding country from the Tower, where the foreign visitors massed in imposing numbers. Special trains conveyed the company to and from Windsor on the Great Western Railway.

The members had opportunity of inspecting a number of works, etc., which offered chemical interest. Among these may be cited the London works of Liebig's Extract of Meat Company, the Power Station of the Underground Electric Railways of London, the National Physical Laboratory at Teddington, various biscuit factories, breweries, at Burton and elsewhere, engineering works, and other chemical works.

Closing Meetings and Resolutions.

Sir WILLIAM RAMSAY presided at the closing meeting on Wednesday morning, June 2nd. He announced that over 3,000 members and 650 accompanying ladies had taken part in the proceedings. From the official returns it appears, however, that less than 1,000 members had attended the meetings of the sections.

The reports of the sections were then read. The only resolutions affecting the medical profession were the following:—The section for physiological chemistry and pharmacology presented the following resolution, which was agreed to:

That the section in future congresses be a separate and independent section entitled "Biochemistry, including Pharmacology."

The following resolution of the section of hygiene was also carried:

That the congress requests the various Governments to nominate a commission to make researches in collaboration with manufacturers in materials used in the ceramic arts, to encourage the use of substances not containing lead; to restrain the use of lead materials and to conduct further researches with regard to protective materials for the hygienic use of those engaged in the ceramic industries.

Two further resolutions, proposed in conjunction with the section of law, political economy, and legislation affecting chemical industry, were deferred, together with the rest of the resolutions emanating from the last-named section, for consideration by the next congress, as no one was present to argue in favour of their adoption.

Dr. TAFFE wished the congress to pass a resolution prohibiting the use of milk-skimming machines in connexion with dairies, but his motion was not seconded.

Various commissions were reappointed, and certain monetary grants were voted.

Next Meeting.

An invitation to the congress to hold the next meeting in the United States of America was given by the Hon. Whitelaw Reid, the American Ambassador, and supported by Drs. Wiley, Professor Meldola, and Professor Baskerville. After various other items of business had been disposed of, a number of delegates from various countries spoke.

THE COMPOSITION OF SOME PROPRIETARY FOOD PREPARATIONS.

TONIC WINES.

VIBRONA.

Messrs. FLETCHER, FLETCHER AND CO., LIMITED, the proprietors of the tonic wine called "Vibrona," have written to us with regard to the analysis of this preparation which we published in the JOURNAL for May 29th, as they take the view that the statements then made may produce an impression unfavourable to their wine. Messrs. Fletcher, Fletcher and Co. wish to point out that the alkaloids in the wine are present in the form of hydrobromides; that the natural quinates, cinchonnates, and other constituents of the bark are retained unaltered by a special process of manufacture; and that it is on account of the particular combination in which the alkaloids exist in the wine that persons can take this wine who cannot tolerate other forms of quinine. They also assert that the figure which we gave for the amount of alkaloids—namely, 0.02 per cent.—should be 0.0285, the latter figure corresponding to the constituents of 5 grains of cinchona bark in 2 fl. oz. of the wine; they have submitted certificates which show that during the fourteen years of its manufacture the strength of Vibrona has been checked by a chemist who is one of the leading authorities on cinchona, who has periodically obtained bottles of the wine through ordinary trade channels, and analysed them, and has reported that he has found the wine to be uniformly of the strength stated. We gladly allow Messrs. Fletcher, Fletcher and Co. to bring forward these points; but it may be pointed out that eleven other wines containing alkaloids were reported on in the same article, and in no case was any statement made as to the form in which the alkaloid was combined, or to the presence or absence of other constituents of the drugs concerned; the analyses only purported to give the proportions of the principal ingredients.

MEDICAL AND SURGICAL APPLIANCES.

Surgical Lamps.

SUPPLEMENTARY to their catalogue of electro-therapeutic apparatus issued last year, the Sanitas Electrical Company, Limited (61, New Cavendish Street, W.), have published a sectional list devoted to the latest developments in surgical lamps. The instruments are chiefly if not entirely of German design, and some of them combine a variety of purposes in the one apparatus. To this class belong the universal electrosopes of Casper and Görl, which with slight adaptations can be used for illuminating seven or eight different body passages. Many instruments having special uses in ophthalmoscopic, pharyngeal, and other examinations figure in the catalogue, and mention should be made of the broncho-oesophagoscope of Dr. Brünings, to which considerable attention has lately been directed. The extraordinary progress made in precision instruments, however, is perhaps best seen in the cystoscope, and the Sanitas Company claim that their irrigation cystoscopes with divided-wall catheter excel other varieties because the double tube permits a continuous flow of liquid into and out of the bladder. In addition to its distinctively trade features there is some general information in the little catalogue on the use of electrical incandescent lamps of different tension in diagnostic investigation.

DIETETIC PREPARATIONS.

Brusson Jeune Diabetic Bread.

WE have received several samples of bread made by the firm of Brusson Jeune, of Villemar, France, which has an agency in London. According to the printed leaflet sent with the bread, it is claimed that it is "of all gluten bread that which, although relatively poor in starch, is the most appetizing, the most nourishing, the lightest on the stomach, and at the same time rapidly diminishes the diabetic sugar." In the typewritten letter accompanying it we are told that the "combination of carbohydrates and proteid present in our gluten bread constitutes a diet from which diabetic patients derive great benefit, this being due to the fact (1) that the flour and the gluten are intimately

combined by the special processes employed; (2) the condition of the starch as the result of the excessive heating to which the bread is subjected during its manufacture; (3) the low percentage of fat; (4) the low percentage of moisture." A further statement that some of the rolls are practically pure gluten is corrected in a subsequent letter, which admits that they contain about 35 per cent. of starch, while others, called "Mignonettes," contain somewhat more; and it is further admitted that the Brusson Jeune's "Diabetic Bread" contains from 48 to 56 per cent. of starch, but, the letter goes on to say, the firm does not rest its claim upon the chemical analysis of the bread, but upon "the results revealed in the urine," and, "while fully understanding the importance of chemical and theoretical analyses of foods intended for diabetic patients, they think it will be agreed that it is upon the results of the urinary analysis that the value of a particular food must stand or fall." We have submitted one of the rolls of diabetic bread for analysis, with the following results:

	Brusson Jeune Bread.	Standard White Bread.
	Per Cent.	Per Cent.
Moisture (212° F.)	9.10	39
Mineral matter	1.00	1
Albuminoids	31.75	6.5
Fat	5.00	1
Woody fibre	2.50	—
Carbohydrates	50.65	51.5
	100.00	

Matters soluble in water 9.15 per cent.

These rolls are palatable, but as will be seen the amount of starch scarcely differs from that of ordinary bread; on the other hand, the gluten and fat are largely increased. We cannot admit that a diabetic food can be judged by us in any other way than by analysis, as the estimation of its effect on patients is too complicated for it to be possible to eliminate fallacies except by its prolonged use over a series of cases, and we know of no physiological reasons for supposing that a bread which contains 50 per cent. starch, readily converted by the saliva, and then reducing Fehling's solution freely, can be of any special utility in the treatment of diabetes.

Sweet Whey Powder.

The dry preparations of milk which are obtainable are becoming very numerous, and they are, as a rule, very serviceable and satisfactory. One of the most recent to come under our notice is the sweet whey powder made by Casein Limited, for the preparation of whey for infant or infant feeding. It is a fine powder, slightly alkaline in reaction, readily soluble in water to a cloudy solution which is free from curd, and in which boiling increases the turbidity. Analysis showed the presence of 12.6 per cent. of protein, 8.04 per cent. of mineral matter (chiefly phosphate), and milk sugar with only a trace of fat. It has an agreeable taste, quite free from sourness. Solution of the powder appears satisfactorily to represent freshly-made whey, and the fact that it can be prepared in two or three minutes instead of several hours may make it useful under some circumstances.

MOTOR CARS FOR MEDICAL MEN.

COST OF RUNNING.

DR. J. BERNARD WALL (Coleshill, Birmingham) writes: I have been driving Siddleley cars for nearly two years, and my experience is entirely contrary to Dr. Furlong's (BRITISH MEDICAL JOURNAL, June 5th, 1909, p. 1365). I do a widely scattered country practice, and cover nearly 10,000 miles a year. During these two years I have never experienced five minutes' delay, and have never driven a horse. When I require any little space I write direct to the works, and always get it by return of post. I began with a 10-12 h.p., out of which I got an average of 25 miles to the gallon, but at the commencement of last November I exchanged it for a 14-h.p. landaulette, which, up to-day, I have driven 5,780 miles, and my repairs and renewals have cost me less than £1. The tyres are the same which came from the works, and look like doing a good many miles yet. It is quite obvious to anyone with any experience of motors that if Dr. Furlong has spent 25 £s. 7d. on tyres, tubes, and repairs, and travelled less than 3,000 miles, there is something radically wrong, and I should think it would pay him well to engage a competent chauffeur at a few shillings a week more money.

B. G. H. writes: Possibly the result of my seven years' experience with motor cars may interest others as well as "T. D. N." I live in probably the most hilly suburb of London, and practise as a general medical practitioner. For the nine years 1895-1902 I worked with two horses, two carriages, and a bicycle, and my average annual expenses for these, including buying and selling and upkeep, came to £249 all told.

Since May, 1902, I have used only motor cars in my practice. I divide my medical motoring into two periods, the first, or expensive period, lasting 2½ years; the second, or moderate period, 4½ years.

During the first period, beginning with the purchase of a new 10-h.p. American car, and including also a second-hand 6-h.p. De Dion, I did not have very good luck. The American car was splendid and a wonderful hill-climber for the first six months, but then it began to go wrong, and the repair and replacement bill became very excessive. The De Dion worked well, but it had no hood.

I paid for these two cars £340 17s. 4d., and sold them for £57 10s., thus losing on them £273 7s. 4d., or an annual average depreciation in the 2½ years of £119 12s. 11d. During this same period my annual average expenses for upkeep, petrol, oil, repairs, man's wages and clothes were £261 16s. 8d., making an annual total of £381 9s. 7d. These cars were sold towards the end of 1904.

In September, 1904, I bought a second 4½-h.p. De Dion, and used that exclusively for 1½ years; and in January, 1906, I bought a second-hand 7-h.p. four-seated Panhard, and I have used these two cars ever since. I use only one car at a time, and of the two the Panhard is used nine-tenths of that time. I paid £310 for these two cars, and deducting what I consider to be their present selling value, though they are decidedly worth more to me, I find that during the second period of 4½ years the average depreciation has been £49 12s. 3d.

My average annual expenses for upkeep, wages, repainting, etc., of the cars for this same period have been £205 11s. 4d., and with depreciation, £49 12s. 3d., £255 3s. 7d., a total average expenditure which compares very closely with that for my horses and carriages already mentioned.

My average annual earning capacity, as judged by "bookings," has hardly altered, but I am enabled to finish work much earlier, and can work with much greater comfort to myself and patients, as there is no horseflesh to consider. Having a vehicle always ready for evening and night work alone makes motoring worth while, and I should not at all care to go back to horses. I can, and do, usually drive myself, and understand the mechanism of my cars, but I keep a man, who cleans the car, does all ordinary adjusting and repairs, comes out with me, and drives when necessary. I am not particularly careful, and certainly not "parsimonious"; but am not needlessly extravagant, nor do I allow my man to be. The average annual mileage has been between 6,000 and 7,000, or about 18 miles a day. I consider "T. D. N.'s" estimate of 12,000 miles as almost impossible for a medical man with many patients to see.

I have taken a car on four of my annual holidays, but I do not recommend this if expense is an object. The figures given, however, include these holidays.

I insure for everything.

As to tyres, I use one studded tyre during the winter on the Panhard, and have tyres retreaded when possible. I have found Michelin and Avon tyres quite good.

I know probably over fifty medical men who use motors; their favourite cars are the following, placed in order roughly, according to numbers used, the first two mentioned being much the most numerous:

De Dions of 8, 6, 10, 15 h.p.	Humbers of 12, 15 h.p.
Panhard's of 7-10, 8, 15 h.p.	Argylls of 12 h.p.
Renaults of 10, 14, 16 h.p.	Sunbeams of 12, 14 h.p.
Darracqs of 8, 16 h.p.	Swifts of 10 h.p.
Rovers of 8 h.p.	Italas of 16 h.p.
Siddeleys of 10, 15 h.p.	Napiers of 24 h.p.

and a few others.

I summarize as follows:

Annual Average.			
	Expenditure.	Depreciation.	Total.
Nine years' horses and carriages	249 0 0
Two motors:			
First period, 2½ years	...	261 16 8	119 12 11
Second period, 4½ years	...	205 11 4	49 12 3
			255 3 7

The annual expenditure for the last 4½ years has been made up as follows, on an average:

	£	s.	d.
Petrol and oil	...	23	16 0
Tyres	...	35	3 0
Man's wages, clothes, etc.	...	70	0 0
Insurance	...	15	11 0
Replacements, repairs, and sundries	...	65	1 4
	205	11	4

Average annual mileage, 6,000 to 7,000 miles.

My final advice is: Get a car of a standard make, and to begin with a good second-hand one. Do not use too large a car. Have two cars, so as to avoid delays while any repairs are done to tyres or mechanism of either car. Carry a Steeple wheel. Learn to understand your cars yourself.

LITERARY NOTES.

MR. MURRAY will shortly publish a work by Dr. David Forsyth, entitled, *Children in Health and Disease*. After treating of the physiology and psychology of the normal child, the book deals with the health of children in elementary and public schools, and with the principles on which the training and moral education of boys and girls should be founded. The State and municipal problems of infant mortality and of the idiot and feeble-minded population are discussed in detail. The concluding chapters are devoted to the various aspects of disease as affecting children.

Messrs. Rebman, Limited, will publish on June 23rd *The Maniac: a Realistic Study of Madness from the Maniac's Point of View*. The book is said to be a faithful account of a genuine attack of acute mania; and the publishers, in a note to the book, give it as their opinion, after careful investigation, that the book is a genuine record of an actual case of madness. The same publishers also announce for issue on the same date a new novel by the author of *Morag, the Scot*, entitled, *Old as the World: a Romance of the Western Islands*, by J. W. Brodie Innes.

It is related, on the authority of Van de Weyer, that at a diplomatic conference Talleyrand pointed to a sentence, and remarked, "I suppose this means so and so." To which the reply was, "Cela va sans dire." Talleyrand quietly answered, "Oui, certainement, mais cela va mieux en le disant." We commend this saying to the attention of those who—say in relating a case, drawing up a report, or writing a letter—omit something which is too readily assumed to be known to the reader. A thing may to the writer's mind "go without saying," but it is seldom that it will not go better by being said.

The mention of Talleyrand reminds us of his niece, the Duchess de Dino, who acted as hostess for him when he was ambassador in this country. In her memoirs, entitled, *Chronique de 1831-1862*, describing Lord Holland, she says he had "une bienfaisance perturbatrice." How well we all know this disturbing benevolence. Doctors suffer from it more than any other class of the community, for charitable persons of all sorts think they have a right to make unlimited calls on their gratuitous services. At the present time the London County Council and many other public bodies are displaying a "bienfaisance perturbatrice" which, unless it is checked by the action of the British Medical Association, is likely to make the struggle for life more arduous to many members of the medical profession.

On June 1st M. Capitan presented to the Paris Academy of Medicine four Peruvian vases belonging to a period before the Incas. On one was represented the head of an Indian who had lost an eye; on another was an admirably modelled figure with both orbits empty. M. Capitan thinks that the figures represented cases of non-leptotic panophthalmia. A third vase showed a person the end of whose nose was cut obliquely; the lower limbs were wasted. On a fourth was a recumbent figure whose nose had also been cut obliquely, while there was a considerable loss of substance on the upper lip. On the right side of the neck was a large mass; the lower limbs ended in stumps. Various explanations of these lesions have been given, some seeing in them the effects of syphilis or tuberculous lupus. Virchow believed them to be due to leprosy. Others think they are the results of amputation of the nose and upper limb done to stop the advance of lesions of some kind. M. Capitan makes no mention of the possibility that they may show the handiwork of the executioner. The mass on the neck of one of the figures, however, would suggest disease.

On May 8th there was issued to the public the fourth volume of the *Belfast Health Journal*, a publication devoted to the promotion of the health of the public. It is now many years since Dr. O'Neill issued his first volume of the *Health Journal*, and it is just a quarter of a century since he began his health crusade in Belfast. In 1884 the population of the city was 215,622; it is now 380,344, while the death-rate has fallen by 3 per 1,000; 70,000 copies of the *Health Journal* have been circulated to teach the public the cardinal doctrine of life—that to ensure health they must breathe fresh pure air, use pure water, eat wholesome food, keep the body clean,

wear comfortable clothing, live in healthy homes, and avoid mental worry. The journal deals with the important subject of primary education and the proper conditions for such work. It points out that, while there are numbers of schools well suited to the needs of the position, there are others which are a positive discredit to public decency and a menace to the health and the lives of the children attending them. Photographs of some of the new ideal schools, such as the "O'Neill Memorial" School, Crossnacreevy, are shown in contrast with others of the old objectionable type. The success of the technical movement in Belfast under zealous municipal control is pointed out, and the proposal is put forward to establish primary education throughout the country similarly under the control of borough or county councils. Another question dealt with is the provision of decent houses for workers, especially in rural districts, where hundreds of labourers have to live in wretched hovels, ruinous to the health of themselves and families. Rural councils are urged to take immediate steps to avail themselves of the Government grant to provide housing conditions that will check the emigration of the labourers, and so secure that workers can be had to carry on farming operations in the country. The issue contains 130 pages, with fine reproductions of many of the national beauty spots of Ireland.

G. J. Guthrie's *Commentaries on the Surgery of the War in Portugal, Spain, France, and the Netherlands, from the Battle of Rolicia in 1808 to that of Waterloo in 1815*, were published in 1853, but, as he tells us in his preface, an introductory lecture appeared in the *Lancet* nearly two years before. In that lecture there are some interesting foreshadowings of abdominal surgery, the developments of which are among the most remarkable achievements of the healing art. He tells the following story:

A respectfully dressed woman of a middle age, by which something between forty and fifty may be understood, came into my room one morning, saying she "was sent to show me her demon." Seeing that I hesitated and did not appear to understand, she added, "the mark of the cut, Sir, made by Mr. —, in my stomach, fourteen inches, Sir, from the end of the breast bone, to the bone below." This was conclusive, and we proceeded forthwith to examine, and there it was sure enough. "Then, Ma'am," said I, "you were regularly opened." "Oh, yes, Sir," she replied, "a lump twice as big as your head was taken out, and the doctors were very kind. One put back my bowels, another arranged my liver and pushed my stomach into its place, but there was some difficulty about what they called my colon." And the lump, I said, "did that bleed?" "Oh, no, Sir, very little; it was tied before it was cut away from my womb, which was shoved back to its place." She concluded by saying, by way of climax, and looking a little demure, "I have had a child, Sir, since that." I could only express my thanks and assure her that she was a lucky woman, but that ladies often did take a great deal of killing—more, I believed, than men. Since that period it is calculated that 150 or 160 operations of a nearly similar nature have been done; one I saw myself precisely similar, the woman dying of bleeding after several days. Obstetricians or accoucheurs, the class of gentlemen who have generally done these things, have recommended, some a cut of ten, some of eight, some of six, some of four inches, instead of fourteen; but whether the cut be longer or shorter, one-third of the sufferers only have escaped with life, and the operation is not considered quite as successful as might be wished, more particularly as the complaint is usually one of great inconvenience and distress, but is not necessarily mortal, sometimes for many years. The great fault, however, is established, and that by gentlemen who are presumed to be the gentlest of doctors, that the whole length of the abdomen of a lady may be laid open by a clean cut, her ovary, and occasionally both, taken out, and that the patient may recover.

Guthrie goes on to say that years before he had said that a mere incision into the belly was not necessarily mortal, except under bad treatment, and he adds that the proof has now been fully given. He proceeds to draw an inference:

When a man has recovered from a wound which has been supposed to have left a hole in his diaphragm, he must not clean a horse, nor tie his own shoes, nor even bend his back, beyond making a bow—I do not forbid that, if he cannot help it. He must eat sparingly at a time, drink less, and sleep as much as possible in a somewhat raised position. When, however, all possible precautions have been taken in vain, and he is distinctly suffering from the symptoms of an internal strangulated hernia of the part supposed to have been injured, and is likely to die unless relieved, what is to be done? Why, you must make an incision through the wall of his abdomen (as the accoucheurs do in this part of the ladies), just over the suspected spot; introduce your hand through this cut; feel with your forefinger for the hole in the diaphragm, and withdraw the strangulated part, even if it should be necessary to enlarge

the hole in the diaphragm by a blunt-pointed bistoury. If it should have formed attachments and cannot be withdrawn, the strangulation may be relieved and the patient survive.

Further on he says:

Wounds of the abdomen are, perhaps, more dangerous than those of the chest, and several points in connexion with them have received the earnest attention of several surgeons of great repute. The general and efficient knowledge of the subject differs, nevertheless, but little from that I have noticed with respect to wounds of the thorax. I have, however, lately seen two or three cases recorded, in which all known principles were successfully resorted to; and I augur from them a most important change in the attention paid, and about to be paid to the treatment of these injuries.

I have recommended you to open the belly of a man to enable you to reach and reduce a strictured protrusion of some internal part of the chest, through a hole in the diaphragm. A friend of mine being in Paris, and understanding that M. Amussat had laid open the back of a lady, in order to enable him to make an incision into her great bowel, above a part strictured and impassable from disease, and has thus saved her life, waited upon him accordingly. Shown into great chamber, he fell into conversation with a very agreeable good-looking lady, profuse in her praises of M. Amussat, of which she seemed to speak so feelingly, as to induce my friend to say that the especial object of his visit was to see a lady on whom he had performed a remarkable operation, which he named. His fair auditor was delighted, declared herself to be the person who had been so operated upon, and, as the speedy arrival of the doctor was uncertain, she, with great good nature, raised her inexpressibles, pulled out the plug in her back, and convinced my friend of the successful result of the operation on her colon. This operation has since been done as successfully in England, and I have very lately seen a case in which the abdomen was opened above the left groin for a similar purpose, the patient, a good-looking middle-aged man, congratulating his surgeon and himself on its successful result.

It has frequently been said that the most heroic qualities of mankind are only developed in times of universal trouble, and a very cursory study of the French Revolution goes far to confirm the truth of this statement. One of the most remarkable features of the period is the sublime heroism displayed by all sorts and conditions of quiet, peace-loving citizens—scholars, priests, and women—heroism of which no one would have thought them capable, and which seems to have been developed suddenly under the stress of circumstances. Several doctors figure amongst these obscure heroes. One of the most courageous was a famous surgeon—Dessault—the head of the Hôtel-Dieu. After the sack of the Tuileries on August 10th he managed to rescue several of the wounded, whom he hid in the beds of his patients in the hospital. The mob invaded the Hôtel-Dieu in search of their victims, but Dessault, with the help of nurses and patients, skilfully evaded all questions and saved them all from certain death. Another doctor who played a part in the drama of the Revolution was Lemonnier, equally celebrated as physician or as botanist. Mrs. Maxwell-Scott in her recent book, *Madame Elisabeth de France*, makes honourable mention of him. He had been one of the tutors of Mesdames Clotilde and Elisabeth, sisters of Louis XVI, to whom he taught botany. He gained the affections of the royal children to such an extent that later, when Madame Elisabeth had her own establishment at Montreuil, and Lemonnier was living close by, a close friendship grew up between the two. The Princess made her old master her almoner in the village, and delighted in sharing his studies, and even his experiments in the laboratory. Lemonnier's devotion to his pupil nearly cost him his head. At the outbreak of the Revolution he held the post of physician to the King, and occupied a suite of rooms in the Tuileries. When the mob broke into the palace they found Lemonnier quietly seated in his library. The infuriated people asked him what he was doing there. "I am at my post," he answered. "I am the King's physician." "And are you not afraid?" they cried. "Of what?" was the calm reply. The old man's courage so astounded his questioners that they forbore to touch him, and merely asked where he wished to go. He answered that he desired to be conducted to the Luxembourg, and a line of pikemen escorted him thither, no one raising a hand against him. "Let him pass," said his escort; "he is the King's physician, but he is not afraid." Lemonnier saw his former patrons again before the end of the tragedy. During his imprisonment in the Temple the King was troubled with an abscess in the mouth, which made him very unwell. He was not allowed to see his

own dentist, but as he grew steadily worse his gaolers became alarmed and sent for Lemonnier. The doctor was given leave to visit Louis twice a day for a week, and one cannot doubt that these visits were a consolation to the unhappy King and his family. Lemonnier had a great respect and affection for Louis as well as for his sister, and was profoundly distressed by their misfortunes. These two examples, taken at random from a score of others, might be multiplied indefinitely, and show us that, side by side with doctors such as M. Souberbielle Bellommc, there were members of the profession who remembered their duty and dared to brave the guillotine in performing it.

Medical News.

DR. R. DEANE SWEETING has been appointed to represent the University of Oxford at the forthcoming Sanitary Congress at Leeds.

DR. WM. STIRLING, Professor of Physiology, University of Manchester, has been elected a foreign corresponding member of the Reale Accademia di Medicina di Turin.

DR. ELLIOT SMITH'S Arris and Gale Lectures at the Royal College of Surgeons of England, which were to have been delivered on June 25th, 28th, and 30th, have been postponed. They will be delivered during the winter months.

SIR WILLIAM BENNETT will take the chair at a conference on the medical inspection and treatment of school children arranged by the Incorporated Institute of Hygiene, to be held on Monday next at 4.30 at 34, Devonshire Street, W.

THE Savings Bank of Milan has voted a grant of £10,000 to the Italian Committee for the study of cancer, on the understanding that the money shall be payable when the proposed National Institute of Cancer Research is in working order.

AT the recent sitting of the Board of Examiners of the Royal College of Veterinary Surgeons, held in Edinburgh, nine students of the Royal (Dick) Veterinary College passed the final examination and were granted the diploma of M.R.C.V.S.

THE Royal Mail Steam Packet Company has told off for Norwegian and Morocco cruises this summer two of its finest vessels, one having a swimming bath in addition to ordinary accommodation. A booklet describing the tours, none of which are expensive either in time or money, can be obtained on application at any of the company's agencies.

THE Council of the Royal Institute of Public Health have awarded the Harben Gold Medal for eminent services to the public health, which they are empowered to do triennially, to his Excellency Professor E. von Behring, M.D., Marburg, Germany, and have appointed Brevet Lieutenant-Colonel W. B. Leishman, M.B., R.A.M.C., Professor of Pathology, Royal Army Medical College, the Harben Lecturer for the year 1910, and Professor Angello Celi, M.D., Rome, the Harben Lecturer for the year 1911.

THE Inter-University Congress, which met in Belfast last year, is to meet in Durham and Newcastle-upon-Tyne at the end of this month. A large gathering of the Students' Representative Council of the universities and medical colleges is expected. Already invitations have been issued by the University of Durham College of Medicine and the Armstrong College to social functions. There will be, in addition to the more serious business of the meetings, the usual sports.

A CRICKET match for the members of the British Medical Association visiting Belfast will be held on Thursday, July 29th, on the grounds of the North of Ireland Cricket Club, which are only ten minutes' walk from Queen's College. Dr. J. W. Taylor has kindly arranged to give luncheon to the teams, and afternoon tea to them and the spectators as well. Cricketers members who are willing to take part in the match are asked to communicate as soon as possible with Dr. J. W. Taylor, Dunelm, Malone Road, Belfast.

COMMEMORATION DAY at Livingstone College was celebrated in the grounds of the institution at Leyton on May 26th, the Master of Trinity College, Cambridge, presiding, and a large number of medical men being among the visitors. The speakers included Dr. C. F. Harford, the principal of the college, who said that in

the last fifteen years public opinion as to the need of missionaries having some medical training had changed, and the Master of Trinity, who, touching on the same point, said that he had had missionaries among his own relatives, and felt that their lives might have been saved had they had the advantage of the knowledge afforded by a residence at Livingstone College. Professor Alexander Macalister said that when the institution first commenced its work he had had some doubt as to the wisdom of the training given; but now, as an old medical teacher, he had thorough confidence in it. A missionary ought to be in a position to render simple medical aid to natives when qualified medical assistance could not be obtained, and to know how to safeguard his own health. He hoped that before long training such as was provided at Livingstone College would everywhere be regarded as an absolute necessity for missionaries. The meeting was also addressed by the Central Asian explorer, Dr. M. A. Stein, who said that he had come specially to bear testimony to the value of the services rendered him during his recent travels in the Himalayas by an old student of Livingstone College. When making for home towards the end of his expedition his feet were so badly frostbitten that he felt it imperative to obtain assistance of some kind. He therefore caused himself to be carried on an improvised litter over a pass between 17,000 and 18,000 ft., and was met by an old student of Livingstone College, the Rev. Sebastian Schmitt, who took him to Len and gave him the attention he required. He had since consulted eminent surgeons both in India and in England, who said nothing could have been better than the conservative surgery carried out by Mr. Schmitt. His left foot had entirely recovered, and the utility of the right foot was far greater than he had any right to expect.

THE annual meeting of the Society for Training Teachers of the Deaf, and for the diffusion of the "German" or pure oral system, was, by the kind invitation of Mrs. Synes-Thompson, held at 33, Cavendish Square, on May 26th. Sir McNeill Bechocroft, Chairman of the London County Council, presided, and in moving the adoption of the report, pointed out that, according to the latest available census returns, there were at least 20,000 deaf and dumb persons in the United Kingdom. The London County Council provided school accommodation for 625 deaf children, of whom about 400 were in day classes and 225 in residential institutions. For these about 65 specially trained instructors were required. The demand for trained teachers was much in excess of the supply, one reason being that the cost of training exceeded that of the training of the ordinary elementary teacher. It seemed remarkable that while the State imposed on the local educational authorities the duty of providing for the teaching of deaf children it gave no financial aid—or at best, inadequate aid—to the training of their special teachers. In these circumstances the work of such colleges as that at Ealing and its sister institution in Fitzroy Square called for support in sympathy and funds from the benevolent to help in supplying this great public need. Dr. Shuttleworth seconded the adoption of the report, supporting the chairman's statements as to the inadequacy of State assistance in the provision of teachers for deaf children, though the instruction of the latter was compulsory by law, and pointing out the danger to the community of the uneducated deaf drifting into the asocial and criminal classes. He referred to a recent case in which a "stone deaf" prisoner, without the benefit of education, had by reason of his inability to plead been, without trial, for his offence committed to prison as "non-sane." Though the prison surgeon did not consider him insane, he still remained in custody awaiting "His Majesty's pleasure," three learned judges having decided that the man's inability to plead constituted "insanity" in point of law. From such a predicament special education would no doubt have saved him. Such a case seemed a strong argument in favour of the beneficent work of this society. The resolution having been carried, Sir M. M. Bownagregre, K.C.I.E., moved the reappointment of the officers, and referred to the fact that no less than 148 teachers had been successfully trained at the Ealing College, which was admirably and economically managed, satisfactorily reported on by the Board of Education Inspector, and capable of even more extended utility if only better supported by private benefactions or public funds. Mr. A. E. Miles is Treasurer, the Rev. A. J. Thompson Honorary Secretary, and Miss E. Hewett, Principal of the Training School at 47, Eaton Rise, Ealing, which receives deaf children for education, besides training teachers.

British Medical Journal.

SATURDAY, JUNE 19TH, 1909.

PUBLIC HEALTH AND SOCIAL CONDITIONS.

THE conditions which at the present day help to build up the fabric of society in highly civilized States are of such a complex character that the social reformer is often in despair when he attempts to modify or to amend the hard lot of his less fortunate fellow beings. If he decides to make himself master of one aspect of the problem he finds that it is so closely interwoven with other aspects that he hesitates to draw conclusions which may ultimately prove to be fallacious. If, for example, he makes himself thoroughly familiar with the administration of the Poor Law, he discovers that he must obtain also a knowledge of the main facts concerning public health; he must, for instance, become acquainted with death-rates and with sickness-rates in different localities, and he must gauge their effects upon pauperism. Then, again, he cannot avoid a study of industrial conditions and the varying conditions of the labour market. Details on all these matters are to be obtained by those who know where to find them, but those who possess the knowledge are comparatively few, so that it was a happy inspiration which led the President of the Local Government Board to commission some of his staff to compile from material which they had to their hands a series of statistical memoranda relating to certain aspects of existing social conditions. The resulting volume¹ is intended "to illustrate in a convenient and readily intelligible form various matters of importance in the study of those conditions such as the growth of population, mortality, and public health administration, the changes in the occupations of the people, the recurring periods of industrial prosperity and depression, pauperism and the action of the Poor Law, local taxation and local debt, and the development of education and thrift." The sections relating to public health were produced under the supervision of Dr. Newsholme, and those relating to the Poor Law under that of Mr. J. S. Davy, while the volume generally was compiled by Mr. C. F. Adair Hore, one of the staff of the Permanent Secretary of the Local Government Board for England and Wales.

The feature of the memorandum throughout is the simple and graphic representation of facts. This is achieved not alone by a liberal use of charts and maps, but by the simplification and explanation of tables, of which there is a very large number. For instance, the varying increase or decrease in the population in the past half-century in the several divisions of the United Kingdom is shown by stating that for every 100 persons living in 1851 there were in 1908 estimated to be 197 in England, 187 in Wales, 167 in Scotland, and only 67 in Ireland. The birth-rate in England and Wales was at its highest in 1876, and calculated as the ratio of the number of births

in a particular year to the total population estimated to be living in that year—that is to say, in the manner in which it is usually calculated—there was a decrease equal to 20 per cent. between 1876 and 1905; but when the calculation is made, as it should be, as a proportion of the number of married women at child-bearing ages, between 15 and 45 years, the decrease in the birth-rate is found to be equal to 27 per cent. in the same thirty-year period. When the illegitimate birth-rate is calculated in the same manner—that is to say, as a proportion of the number of unmarried and widowed women at conceptive ages—there is seen to be a fall from 14.6 per 1,000 in 1876 to 7.8 per 1,000 in 1907.

The relationship between the death-rates, institutional treatment of disease, pauperism, prices and wages is very graphically shown in a chart. Assuming that all these factors stood at 100 in 1869, the death-rate from all causes in 1907 was equivalent to 72, and from phthisis to 47; the amount of pauperism would be represented by 55, while prices have fallen to 80. On the other hand, wages have risen to 140, and the amount of institutional treatment to 225. The satisfaction which is aroused by the gratifying elements in these records receives a serious check upon turning to the details of infantile mortality, for during the whole of the second half of the last century there was practically no diminution in the appalling rate of death among young children which obtained in the first half. The genuine efforts made in the past few years to reduce this mortality are now having some result, for in the present century there has been a fall in the infantile mortality rate of about 20 per cent.

A very interesting and concise account is given of the Public Health administration of England and Wales. The powers and duties of the central and the local authorities are recorded with a simplicity so engaging that those who read of them for the first time will wonder how it is that insanitary conditions are permitted to exist in face of the fact that such acknowledged powers of abolition exist. The Local Government Board, we are told, is empowered to receive complaints as to the default of local sanitary authorities in providing sewerage or (in certain cases) water supply, and in enforcing the provisions of the Public Health Act, which it is their duty to enforce, and it may, after local inquiry, compel them to discharge their duty in these matters. The medical officer of health and the inspector of nuisances, it is stated, occupy an important place in local sanitary administration. This is an admission of some importance, for it has not infrequently happened that these officials have not received the support from the central authority to which they considered they were entitled.

The account of the development of institutional care in England and Wales includes some very striking facts. In 1871 there were in the whole country 13,706 persons in hospitals, and this number had increased to 35,160 in 1906. In the former year 2.6 per cent. of the total deaths occurred in hospitals, but in 1906 this percentage was 6.6. In London the increase was not so great during the same period, for in 1871 there were 5,228 persons in the metropolitan hospitals, in which there occurred 6.5 per cent. of all deaths, while in 1906 there were in these institutions 10,611 persons, and the deaths in them constituted 14.3 per cent. of the total number registered in London.

In the section of the memorandum which deals with pauperism and the Poor Law we are told that in the

¹ *Statistics and Memoranda and Charts prepared in the Local Government Board relating to Public Health and Social Conditions.* London: Wynaf and Sons; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby, 1909. (5s.)

last fifty years every class of pauper in proportion to population has declined, the decrease being about 74 per cent. in the case of children and able-bodied adults and 44 per cent. in the case of the aged and infirm. In the year 1849 the number of adult able-bodied paupers was 13.5 per cent. of the total population, but in 1908 this percentage was 3.5. The cost of poor relief presents several features of interest. Between 1850 and 1907 the cost per head of the population has risen from 5s. 11d. to 7s. 9d., but the cost per £ of rateable value has fallen from 1s. 6½d. in the former year to 1s. 4d. in the latter. The increased expenditure is, no doubt, in part accounted for by the very large number of lunatics who are now cared for in asylums compared with those who were so treated fifty years ago. The additional care bestowed upon the sick poor and the increase in the number and character of institutions accounts for still more of the increase.

It is impossible to dip more deeply into this extremely interesting and instructive document, which is certainly one of the most useful Blue Books ever issued from a Government department. Although we have been able only to skim the very topmost layer of the cream, we have endeavoured to show that it is a volume which contains within its pages data and material which will materially assist in the solution of many urgent social problems, and, while pointing the right direction to be taken, will also prevent the selection of dangerous or altogether inappropriate paths.

TUBERCULOSIS IN INDIA.

THE great attention paid during recent years to diseases peculiar to, or specially prevalent in, the tropics has been accompanied by a comparative neglect of the study of the havoc wrought by certain common world-wide diseases in hot countries. One of the most important of these is tubercle, to which, in its relation to India, attention has recently been directed prominently by the publication in the *Indian Medical Gazette* of series of papers read before the Medical Section of the Asiatic Society of Bengal. The interest aroused in the subject is shown in the fact that the reading of these papers and their discussion occupied three monthly meetings. The outstanding feature of the debate was the conclusive and unanimous evidence adduced regarding the great frequency of tuberculosis, especially phthisis, in Bengal, and its high mortality. The statement made by the late Dr. A. Crombie at the International Congress on Tuberculosis in Berlin in 1899, to the effect that the disease was quite rarely met with in natives of India, seems to have been completely disproved. Thus Lieutenant-Colonel G. F. A. Harris, I.M.S., in his introductory address, stated that 10 per cent. of the admissions to the General Hospital, Calcutta, in 1882-4 were for pulmonary phthisis, while after ten years' recent experience at the Medical College Hospital, mainly with Indian patients, he had come to the conclusion that the disease is one of the commonest and most fatal in that city. This view is fully confirmed by an analysis of *post-mortem* records of that hospital for twenty-six years contributed by Major L. Rogers, I.M.S.; no less than 17 per cent. of the deaths were directly due to tuberculous disease, while 8 per cent. more showed latent or healed tubercle in the lungs. Thus no less than 25 per cent. of the bodies revealed evidence of this disease, and the percentage would

doubtless have been higher still had the condition of the lymphatic glands been regularly recorded. Major J. Mulvaney found that as many as one-fifth of the deaths in Bengal gaols were from phthisis, and that nearly all occurred among prisoners admitted with the disease. Another interesting point brought out is the comparative rarity of surgical forms of tuberculosis, which were observed in only 0.45 per cent. of the total *post-mortem* examinations, and in only 2.2 per cent. of the total admissions to the surgical wards at the Medical College Hospital. Major L. Rogers attributed this to the great rarity of bovine tuberculosis in India as compared with Europe, a view which lends important support to the conclusions of the Tuberculosis Commission regarding the frequency of infection through cow's milk in England. The evidence of the *post-mortem* records and the vital statistics of Calcutta also agreed in showing that the highest tuberculosis-rate was found among females, and especially among Mohammedan women, who are so closely confined in overcrowded houses and have less opportunity of getting out in the open air than any other class. The analysis of the *post-mortem* records also showed that tuberculous pericarditis and pneumothorax were more common and tuberculous meningitis less common than in temperate climates. All these data reveal a very great prevalence of tuberculous disease in India, while the fact that in an inquiry into the real causes of deaths returned under the elastic heading of "fever" in an unhealthy malarious district of Bengal, no less than 9 per cent. were found to be certainly due to phthisis alone, makes it clear that tuberculous diseases in this province produce a mortality second only to that due to pneumonia and to malaria and kala-azar combined. It is also now known to be exceedingly prevalent in the United Provinces and Central Provinces, as well as in Bombay and Madras; in short, over nearly the whole of India. It is probably less prevalent in the dry Punjab, although exact data appear to be wanting on that point.

Enough has been said to prove that tubercle is a far greater scourge in India than, for example, such dreaded diseases as cholera, small-pox, and dysentery. It would seem that this fact has not hitherto been fully realized, for otherwise some attempt would certainly have been made to introduce sanatorium treatment which is even more necessary in India than in Europe, on account of the rapidity with which the disease progresses in the hot weather and rainy seasons in the sultry plains of Hindostan. The selection of a site which will present favourable conditions for the treatment of phthisis at all periods of the year is a matter of some difficulty. The only places which have been suggested in Bengal are Darjeeling and the plateau of Chota Nagpur, but in the opinions of competent men who contributed to the debate the former is too wet and cold at certain seasons, and the latter too hot for several months. Those who have had many years' experience of sending tuberculous patients to different places in India seem to be agreed in considering Almora, in the Kumaon Hills of the United Provinces, as the most suitable place for starting a sanatorium. It is at a medium elevation, and is protected from excess of rain by higher ridges to the south, and is very sunny for a hill station. When once the benefits of treatment in a well-managed sanatorium become realized in India, doubtless many wealthy Indians will come forward to endow similar institutions in different parts of India, and so in time something may be done for the

successful treatment of the disease in its early stages, and further infections will be lessened by removing the dangerous patients from the too often overcrowded houses of Indian cities. As a result of the discussion a resolution was unanimously adopted to the effect that the Medical Section of the Asiatic Society of Bengal was of the opinion that it is an extremely common cause of great suffering and mortality, both among the European and Indian communities, and therefore ventured to call the attention of the Government of India and the local Government, to the urgent necessity for providing a properly equipped sanatorium for the treatment of early phthisis, such as has now been provided with most satisfactory results in nearly all civilized countries.

RETARDATION OF METABOLISM.

PROFESSOR R. STAHELIN, in a paper founded on observations made in the university clinic of Professor His in Berlin,¹ has sought to arouse fresh interest in what he believes to be the overlooked importance of retardation of metabolism in certain conditions, a theory which a few decades ago was much talked about, but has gone out of fashion because it was shown by careful research that metabolic processes are more constant than had been assumed.

Stachelin holds that there are reasons for its rehabilitation, at least to a certain extent, on the ground that certain substances hinder the destruction of others. Thus fat, when given with albumen, retards the appearance of nitrogen in the urine, and this effect is to be observed in certain diseases—diabetes for example. Again, according to Falta and Gigon, cheese retards the nitrogen excretion in diabetes, and Stachelin observed the same thing in obesity. The curve of the elimination of purins in gout can, he thinks, best be explained by accepting the theory that there is a retardation of the nuclein metabolism in this disease. A similar condition occurs in alcoholism, diabetes, and lead poisoning. Mohr has maintained that sugar is burnt off more slowly in diabetes, and if its consumption is diminished its destruction should be slowed, but this has not been proved. Combustion may be slow but complete, as in obesity, or it may be incomplete. Dogs from whom the thyroid has been removed show slow carbohydrate metabolism. Waldvogel believed he had proved that in obesity the transformation of beta-oxybutyric acid into acetone is retarded, but his results have not been confirmed. Raising the external temperature has the effect of diminishing the production of heat in warm-blooded animals, but beyond a certain point the external temperature remains without effect, indicating that there is a minimum which cannot be altered.

Any great retardation of consumption must produce marked effects, as is seen in the only universally admitted pathological condition in which it is known to occur, namely, where the function of the thyroid gland is depressed. Stachelin, Hagenbach, and Nager studied the case of a boy who had had a goitre excised twelve years previously, and who in consequence had remained stunted in growth, was thin, ate little, but was perfectly intelligent. The oxygen output was found to be only 70 per cent. of that of a healthy child of the same age; thyroid feeding raised it 25 per cent.

and the case is sufficient to prove that a reduction of oxygen consumption may occur.

Cases have been observed in which men have been able to maintain their body weight on very low diet. Such a case was studied by Pettenkofer and Voit, who proved that there was diminished excretion of CO₂. In oesophageal occlusion from injury, Fr. Muller and Nobelthau found that the body adapted itself to a minimum of food, and Magnus-Levy, in a case of voluntary starvation, where the body weight was reduced to 36 kg. (72 lb.), observed that the oxygen consumption was very small, but when food was taken in proper quantities oxygen was again consumed in normal amount. R. O. Neumann, in observations on himself continued over months and years, found that his body weight remained the same on very varying quantities of food, and Chittenden's experiments show that when nitrogenous food is diminished the demand for it is also reduced. Falta, Rubner, and others have shown that this is true also of animals, but it is not known how far this capacity extends, certainly not to all animals or men, and it is probably less frequent among the latter. Some convalescents show diminished oxygen consumption, others do not. In diabetes most patients have a normal or even increased oxygen consumption, but some show a decided reduction, and can bear a reduced diet without loss of weight. Van Noorden believes that such patients are always ill nourished, but Stachelin doubts the invariable truth of this, and cites the case of a patient weighing 67 kg. (134 lb.) who maintained his body weight on a dietary containing only 30 calories per kilo.

Gout, diabetes, and obesity are the conditions in which slowing of metabolism is observed, and these are the diseases long ago styled "*Maladies par ralentissement de la nutrition*" by Bouchard. He was unable to bring forward sufficient evidence to establish this theory, but it appears that retardation of metabolism is not so uncommon as has been assumed, and it is of great theoretical interest that it should occur in certain diseases of metabolism and in connexion with the depressed functions of certain glands (thyroid and ovaries) which have internal secretions. There are, therefore, grounds for hoping that the experiments of Falta, Eppinger, and Rudinger on the influence of these organs on the rate of katabolism may throw light on the origin of these diseases.

The knowledge of the retardation of nuclein metabolism is of great practical importance in the treatment of gout, while the fact that many diabetics tolerate diminished food supply should overcome our fear of underfeeding these cases, and should allow us to venture in difficult cases to try the effects of reduction of nitrogenous food, even when the distinctly reduced diet possesses an insufficient caloric value.

THE ANNUAL MEETING.

At the end of the JOURNAL for this week (pp. 1521, 1522, 1523, and 1524) will be found a form for the use of members who propose to attend the Annual Meeting of the British Medical Association in Belfast next month. If the form is filled up and returned to the address shown, a voucher or vouchers will be issued from the central office, giving the right to the special terms which have been arranged with the railway companies. A return ticket will be issued at a single fare and a quarter, and this year negotiations with the railway

¹ *Deut. sch. med. Woch.*, 1909, No. 14, p. 77.

companies have resulted in a special concession, which is that the return tickets at the reduced rate will be available from Thursday, July 22nd, the day before the Annual Representative Meeting, until the end of August. This extension will allow members holding return tickets to make an extended tour in Ireland, and to visit some of the places described in the article published in the JOURNAL last week (p. 1422). On the back of the form is a list of hotels, and on the next succeeding page is a list of lodging-houses in Belfast, with a scale of charges: members are requested to communicate direct with the persons whose names are given in the list, or with the managers of the hotels mentioned. The early receipt of the form stating the intention to be present will greatly facilitate the work of the local committee, and, as has previously been pointed out, it is desirable to secure rooms at an early date. The agenda paper of the Annual Representative Meeting, so far as it could then be settled was published in the SUPPLEMENT for May 22nd, and the programme of the general meetings and of the Sections was last published in the SUPPLEMENT of last week, but we may recall the fact that the President-elect, Sir William Whitla, will be inducted on Tuesday afternoon, July 27th, and will deliver his address on the evening of that day in the Assembly Hall. The Sections will meet on Wednesday, Thursday, and Friday, July 28th, 29th, and 30th.

THE MEDICAL TREATMENT OF SCHOOL CHILDREN.

THE London County Council, as was stated in the JOURNAL of June 12th, decided, in opposition to the majority report of the special subcommittee of experts appointed to consider the means of providing for the treatment of school children found defective, to attempt to utilize existing institutions—that is to say, hospitals and dispensaries. The education officer thereupon issued a circular to the London hospitals, asking whether they were willing to co-operate—in other words, whether they were prepared to place an additional burden on their medical staffs, and increase the already intolerable amount of hospital abuse. We published in the same issue a circular letter addressed by the Council of the Metropolitan Counties Branch to the members of the medical staffs calling attention to the significance and consequences of this action of the County Council. That some, at least, of the hospitals will agree with a light heart to an arrangement which will inflate their statistics of out-patient attendance is tolerably certain. Indeed, from a note published at p. 1504, it will be seen that the Great Ormond Street Hospital for Sick Children has expressed its willingness to provide treatment for twenty-five school children a week. Naturally the Education Committee recommended the acceptance of an offer which "would not involve the Council in "any expense." This will doubtless be satisfactory to everybody, except the doctors; and of course their willingness to bear the burden imposed on the County Council by the State is taken for granted. Their vicarious charity is apparently held by some members of the Council to be an act of reparation, as one ornament of that bright exemplar of municipal bodies said that it was the doctors who were responsible for the fact that the children require to be treated, and asked, with a fine assumption of indignation, if it was suggested that the Council should make amends for the misdoings of the profession! We suppose the next proposal will be that a special rate should be levied on the medical profession to defray the cost of the treatment.

AN INDEX OF CURATIVE SKILL.

MR. FRANCIS GALTON in his early days was a medical student, and in his *Memories of My Life* he has some interesting remarks on the practice of the healing art. He says: "The opinions held by the students 'about the several physicians and surgeons were 'curiously guided by a mixture of loyalty and 'irreverence. There was no doubt of the fact that "M., one of the doctors, who never professed or had "a claim to scientific acquirements, got his patients "out of hospital more quickly than any of his "colleagues. His treatment was as simple as that "of Dr. Sangrado, though of quite another kind. "It consisted of a strong purgative followed by low "diet, and a subsequent feeding up as soon as the "fever had gone. The composition of his drench "never varied; a big bottle of it was made every "morning in the dispensary, in readiness to be served "out. It was so cheap that the overplus could be "thrown away and a fresh infusion made the next day." Mr. Galton goes on to express the opinion that it is desirable that some "index of curative skill" should be awarded to doctors, based on their respective hospital successes. He says he has often amused himself with imaginary schemes to this effect. If it could be compiled truthfully, he thinks it would be an excellent guide to those who wanted a doctor, but were doubtful whom to consult. A high index of curative skill would serve as a measure of merit, and the fee to the doctor might be regulated by its height. This may seem fanciful, and it is to be feared to attempt to weigh what is imponderable would lead to all sorts of fallacies in theory and to undesirable results in practice. It is, however, within the experience of every one who has watched the practice of physicians and surgeons at a hospital, or of general practitioners in town or country, that there is a difference between one man and another in curative skill, and that it is by no means always the most "scientific" who cure most. We have ourselves had occasion to observe that in surgery the results achieved by certain men were notably inferior to those of others not to be compared with them in point of knowledge or experience. It has been suggested that in the case of operators the hand, or rather the way in which tissues are handled, may have something to do with the course taken by the wound. In medicine and general practice, the difference in curative skill is less easily explained. It is true, as Professor Osler says, that the best doctor is the one who gives hope. But besides this there must be some subtle instinct in the adaptation of means to the end which leads one man right where another goes astray. Sometimes a doctor may unconsciously be ahead of his day, as when Antonius Musa cured Augustus of a complication of ailments by cold baths. Dr. De Lisle, in a paper read at the annual meeting of the New Zealand Branch of the Association, and published in the *New Zealand Medical Journal* for February, relates that in the Thirties there was a physician at St. Thomas's Hospital who treated his fever cases much as they would be treated to-day. The students thought him an old woman, would not go round the wards with him, and took out their lectures in the practice of physic at Guy's. A gentleman whom Dr. De Lisle knew, who got his diploma in 1836, told him he considered himself unfortunate in being appointed clinical clerk to the physician in question; nevertheless, he observed that the death-rate was smaller in his wards than in those of the other physicians, and that while other men's patients were sitting over the fire spitting, his patients were out of the hospital and at work. We have ourselves known a specialist who was very successful in curing cases of uterine displacement by feeding, with little or no local treatment. His assistant

confessed that he thought his chief an old fool, but he faithfully carried out orders, and was astonished by the results. It would be interesting as well as important to ascertain exactly in what "curative skill" consists, so that the power could be cultivated. We fear, however, that it depends on some inborn personal quality which cannot be communicated by teaching.

A NATIONAL HOSPITAL.

TURNING over recently the pages of an early edition of *Burdett's Hospitals and Charities*, the following passage caught one's eye: "The most interesting of this group (miscellaneous hospitals) and the best is the National Hospital for the Paralysed and Epileptic. It treats a very extensive class of patients with an efficiency and success which leaves nothing to be desired." These words are as true to-day as when written some twenty years ago, for the institution has well maintained its promise and has claims to the title of "national," such as cannot be equalled by any other hospital in the country. For a long time past it has been a Mecca for post-graduate students from all parts of the British Empire, and probably does more than any other individual medical institution in these islands to maintain the reputation of British medicine at a high level among our foreign colleagues. The patch of the field of medicine which it has made its own is exceedingly difficult to cultivate, and must prove absolutely sterile, both in therapeutic results and in acquirement of knowledge, unless tended in a scrupulously scientific spirit and with never-failing courage. These have always been forthcoming, and the impress of the work done in the institution may be found in nearly every journal and textbook dealing with medical science. There will be a general hope, therefore, that its jubilee appeal will meet with a good response. The objects were explained at a festival dinner at the Mansion House last week by the chairman of the evening, the Lord Mayor, and by the treasurer of the hospital, Mr. Frederick Macmillan. A desire for more working space and for greater stability in finance represents them in a summarized form. The need of the latter is not the outcome of recklessness in the past, for it was at this institution that the possibility of bringing about material change in domestic management of like institutions was first recognized, with results which have been more than once quoted in these columns in articles on hospital administration. The desire for more space is also quite natural. Its consulting rooms, used as they are as places of post-graduate study, have to be unusually large, and as so many of the patients are helpless more dressing-rooms are required than are elsewhere found necessary. Modern developments in physio-therapy have also helped to create a demand for further space; exercises form now an important part of the treatment administered, and a new room in which to conduct them is needed. Nor are the present quarters for nurses what they should be in a leading hospital. The sleeping quarters are crowded, and the living rooms small and gloomy. All the improvements thus indicated to be required can be provided for about £50,000, which sum would likewise suffice to put the finances of the hospital into a satisfactory position. The sum collected in the room at the Mansion House was not as satisfactory as it might have been, but it may be hoped that between now and the date at which the King has promised to visit the hospital in November the whole sum will be in hand. Meanwhile, and as a further stimulus, H.R.H. the Duchess of Albany is to receive purses at the hospital in October. Part of the hospital is a memorial to her late husband, the youngest brother of the King, and she

is taking an active part in promoting the success of the appeal. Every penny contributed will go direct to the hospital, as she has established an expenses fund to pay for printing, postage, and other connected outlay.

SPEECH FRIGHT.

SIR JOHN BYERS has kindly sent us a very interesting addition to the growing mass of testimony and opinion on this subject which we continue to receive from various quarters. In an address delivered by him to the members of the Literary and Scientific Society of Belfast on January 25th, 1906, and reprinted as a pamphlet, Sir John Byers discusses with keen appreciation the qualities of the late Lord Dufferin as a public speaker. Referring to an address delivered by Lord Dufferin to the students of Queen's College, Belfast, Sir John Byers gives some extracts which bear directly on speech fright. We reproduce some of them here, in the hope that they may be useful to those to whose lot it falls to speak in public. Lord Dufferin said: "No great orator has ever lived who did not feel very nervous before rising to his feet. I have often seen the legs of one of the most effective and heart-stirring speakers in the House of Lords, to whom that assembly never failed to listen, shake like an aspen leaf during the delivery of the first few sentences of his speech [Lord Dufferin told Sir John this was "Lord Derby"]; and should the young speaker feel his tongue grow twice too big in his mouth, and curl itself inextricably round one of his canine teeth, he may console himself with the conviction that he possesses one at least of the characteristic qualities of a great speaker." Lord Dufferin himself was always nervous about speaking, and in his later years the thought of having to speak lay heavy on his mind beforehand. In this respect he resembled John Bright, whose sister, Mrs. Lucas, told Sir John Byers that he was always nervous when rising to speak, and his friends knew beforehand from his preoccupied manner when he was likely to deliver one of his great orations. Lord Dufferin went on to insist that no very good speech was ever made without a considerable amount of preparation, at all events, until long practice had so cultivated the speaker's faculty as to render the art of thinking aloud with fervour and precision a second nature. Even so, he said, he had heard a Lord Chancellor break down and a Prime Minister lose the thread of his discourse. He explained that by preparation he did not mean learning a speech by heart, but the saturation of the mind with a knowledge of the subject and then the construction, not necessarily in writing, but in the mind, of a well-knit skeleton of the argument or exposition; finally when out walking or in the solitude of one's own room, the language in which the ideas may most fitly be clothed should be considered. "A crowded street," said Lord Dufferin, "is not a bad arena for this exercise, as it accustoms you to abstract your thoughts from outward objects, and will render you proof against the discouraging smile of an over-critical opponent. Should you wish to go a step further, and embody in sound the thoughts that burn within you, you can always fall back upon the wandering stars for an audience. A very distinguished member of the House of Commons communicated to me years ago in the hunting field the plan which he adopted, and certainly in his case the result was extraordinarily effective. He said that when about to make an important oration he used to write down what he intended to say as rapidly as he could on successive sheets of paper, which he threw

"into the fire the moment they were filled, without reading them over. This process he repeated seven or eight times, and, as a consequence, he found when he repaired to the House that, in no sense dependent upon his memory for a sentence, these preliminary canters over the ground to be traversed had supplied him with a fecundity of expression and a lucidity of ideas to which otherwise he might never have attained. At all events, if you ever put a speech on paper, don't let the copy slip out of your pocket." Speakers differ greatly in regard to the manner of preparation. Some write out the whole speech and deliver it, like Sir James Paget, "paragraph by paragraph, sentence by sentence, word for word, commas and all," as Huxley once said in his presence. Others, like Huxley himself, will write out a speech and then deliver something which in wording at least is wholly different from the manuscript. Others, again, jot down a few headings and speak from these. As for us, to whom we confess, the orator is a dangerous nuisance—for he appeals not to the reason of the individual but to that most mischievous of social forces, the passions of the mob—the rule we would impress on speakers is to have a message to deliver, to do so as briefly and in words as simple and direct as possible, and to sit down. It would be well if speakers would follow the hint given by a man of the world for visitors, "When you have made a good impression, go away."

PICTORIAL INSTRUCTION IN HYGIENE.

MEDICAL officers of health are only tardily appreciating the value of pictorial representation as an aid in teaching hygienic habits. The advantages of appealing to the popular fancy by means of a picture rather than by printed words, however simply expressed, are sufficiently obvious not to require stating. A good example of what may be done in this direction is to be found in a handbill and poster issued by the New York State Department of Health. In a series of pictures those who are consumptive are shown how they are most likely to be cured; how they may live with others with safety, and in what way they are a source of danger to those who are well. The non-consumptives are shown how they may safeguard themselves against the disease. The pictures are being published in this country (with the permission of the owners of the copyright) by *The Medical Officer*, a newly established journal for medical men in the Government and municipal services. Those medical officers of health who advise their authorities to purchase a supply of these picture placards, either for general distribution or for public display, may feel assured that the money laid out has been wisely expended.

ILLUMINATING ENGINEERING SOCIETY.

THE "Illuminating Engineering Society" was formally established on May 25th with the object of correlating the divergent interests of the architect, the illuminating engineer, the medical man, and the physiologist. The society exists for the purpose of advancing the theory and practice of illuminating engineering and for the dissemination of knowledge, by the reading and publication of papers, the holding of discussions, and the participation in or actual holding of international exhibitions and congresses. A noteworthy feature is that the constitution of the society has been designed to secure the necessary representation of all the interests above mentioned. The need for some such society is apparent to those who have studied the progress of modern illumination. Legislation on the subject is so limited as virtually to be non-existent. Thus, in the report of

the Chief Inspector of Factories and Workshops for 1908, just issued, one of the inspectors states with reference to illumination in factories, "We have no statutory provision to rely upon." Legislation is urgently needed both as regards intensity and quality of illumination. Want of light in factories is a common evil, resulting in inefficient work, in an increased number of accidents, and in general hygienic unfitness; and while bad illumination should be made impossible in the interests of the worker, it would be found that the result of wise legislation on the subject would have most satisfactory economical results. The case against bad illumination can be made out with even greater force when the position of the schools is considered. As has been repeatedly pointed out in our columns, the printing of school books often leaves much to be desired, and when to this evil that of inefficient illumination is added, it is hardly surprising that the most serious results are caused to the children's eyesight and to their general health. It is essential that both natural and artificial illumination up to a satisfactory standard should be made compulsory. Inefficient illumination is the most serious evil that the society will have to combat. But in the near future a more insidious evil will have to be attacked. Direct illumination by means of gas and other illuminants is rapidly disappearing, giving place to indirect methods, such as the heating of mantles to incandescence by the gas, and to the production of high temperature effects by filaments and arc lights by electricity. With the increase in the temperature of the source of illumination the quantity of ultra-violet rays emitted has rapidly increased, and Drs. Schanz and Stockhausen, who are still working on the subject, maintain that artificial illuminants are more trying to the eyes than natural light, owing largely to their very much higher percentage of ultra-violet constituents. The continued subjection of the eye to ultra-violet light is said to cause the lens to become fluorescent and eventually opaque, and glassworkers' cataract is attributed to the action of the ultra-violet rays given out by the molten glass. A glass can now be obtained commercially which cuts off the ultra-violet rays without, it is said, seriously interfering with the brilliance of the light supplied. The new society will no doubt consider how the use of these high-power illuminants may most efficiently be controlled. Mr. J. Herbert Parsons, D.Sc., F.R.C.S., is chairman of the Executive Committee, and the society has already received influential support. All further information can be obtained from the Honorary Secretary, Mr. Leon Gaster, 32, Victoria Street, S.W.

PUBLIC HEALTH IN EGYPT.

IN view of an attack which has recently been made by the *Egyptian Daily Post* on the Public Health Department of the Ministry of Interior in Egypt, an abstract of the birth and death returns for last year, which has reached us, is of special interest. The native population of Cairo at the middle of last year is estimated at 657,438, the birth-rate being 47.5, the general death-rate 34.6, and the infant mortality-rate 282 per 1,000. In Alexandria the native population is given as 337,816, the birth-rate as 44.9, the general death-rate as 30.0, and the infant mortality-rate as 259 per 1,000 births. The same statistics regarding the foreign population are of no interest, as they are calculated on the census of 1897. As regards particular diseases, 269 cases of small-pox were notified in Cairo, with 95 deaths; 23 of these were amongst foreigners; while in Alexandria the notifications were 35, and the deaths 19, of which 5 were amongst the foreign population. In Cairo the typhoid deaths greatly exceeded the typhoid notifications, the former

being 183, and the latter 148. Of these deaths, 27 were amongst the foreign population. In Alexandria, the same disease caused 99 deaths, 23 of the latter being cases amongst foreigners. There was also a good deal of typhus, 359 deaths being due to this cause in Cairo and 9 in Alexandria. Altogether, 11 foreigners in these two cities died from this cause. As for plague, the return for the whole of Upper Egypt is 780 deaths, of which 57 occurred in Alexandria, 15 of these being among foreigners. In Cairo no cases of the disease seem to have occurred. As regards the attacks of the paper mentioned, these, so far as we understand them, would seem to be a charge that the statements commonly sent to Europe by a news agency (which apparently claims to base its reports on official information) habitually minimize the extent to which the principal zymotic diseases prevail in Cairo and elsewhere in Egypt. This is a point on which the present report throws no direct light, but it may be said that while the report does not indicate an ideal state of affairs in Egypt, it at least does not tend to support the belief that Egypt suffers more from zymotic diseases than is usually believed to be the case. A death-rate of 34 per 1,000 is high, but not much higher than that returned by some highly civilized cities in other countries. In examining the returns it must be borne in minds that the term "foreigner" does not relate merely to Europeans, but covers Syrians, Greeks, and all persons who in one way or another are enabled to get enrolled at the Consulates, and thus secure whatever benefits arise from the capitulations.

DEAF-MUTISM.

SHOULD a philosopher of the far future ever chance to amuse himself by classifying each past age according to its seeming mental attributes, the term "priggish" is not unlikely to fall to the lot of the present period. Not only is the voice of the *laudator temporis acti* rarely heard in the land, but there is a general disposition to regard all things good—all the scientific and sociological attainments of the hour—as the product solely of those now living. The medical profession is by no means free from the tendency in question, and for this reason, if for no other, habitual study of the history of medicine is to be commended. It is true that there are some difficulties in the way, since an ideal textbook dealing with it has yet to be written. Nevertheless, valuable contributions to some future treatise on the subject are constantly to be found in current literature. A case in point is a paper recently published by Dr. J. Kerr Love of Glasgow¹ for, though its primary object is to show that the time has come for a new departure in the after-treatment of deaf-mutes—steps being taken to encourage old pupils of deaf-mute schools to consort with the normal members of the community—it incidentally relates much that is not commonly known about the development of oralism. For this, as for so much else, Germany often gets credit which is not its due. The dumb were taught to speak, the deaf to lip-read over a hundred years ago in England, and the method only seems new because sign language—which is less laborious to teach—practically displaced oralism during the first half of last century when the utility of educating deaf-mutes was at length beginning to gain general recognition. For the rest, the evolution of ideas concerning the deaf and dumb, if slow, has been fairly steady. At first, perhaps, the idea of protection mainly predominated, but side by side grew recognition of the practical value of education, and it is now known

that deaf-mutes, if properly trained, are likely, individual for individual, to be as independent of assistance as normal members of the community. It is a Frenchman, the Abbé de l'Épée, who should, perhaps, be regarded as the parent of the present attitude towards deaf-mutes, for though he does not seem to have appreciated the full possibilities of what he was doing, he started a public school for deaf-mutes in 1760, nearly twenty years before any one else thought of doing so. Then followed in turn a school at Vienna, one at Meersburg in Baden, one at Bordeaux, and finally, in 1788, one in Berlin. The Abbé de l'Épée's school was taken over by the Government during the Revolution, but the others were from their inception Government institutions. In Great Britain the work, like most other enterprises of an analogous kind, depended until quite recently on private philanthropy. First came the British Asylum for the Deaf and Dumb, in the Old Kent Road in 1792, then a similar place in Henderson Row, Edinburgh. In Ireland, the first public institution was started in 1831. As things now are, the education of the deaf and dumb is compulsory and since the year 1890 in Scotland and 1907 in England, the ratepayers have been responsible for its whole cost. That deaf-mutes may be so educated as to become capable of holding leading positions in business houses is clear from the letters from old pupils of deaf-mute schools printed by Dr. Love.

ACTINOTHERAPEUTICS.

A RESEARCH studentship in actinotherapeutics, of the annual value of £300, to be known as the Douglas Research Studentship, has been established at Guy's Hospital; the first incumbent will very shortly be appointed, and will be required to take up his duties on July 15th. The Douglas Student, who must possess a registrable qualification, will be required not to hold any other office or engage in any occupation which would prevent him from devoting himself with due diligence to the prosecution of original research. His investigations, unless otherwise specially provided, are to be carried out at Guy's Hospital, under the supervision of the surgeon to the actinotherapeutic department. The student will be appointed for one year, and will be nominated by a special board of electors. Further particulars will be found in an advertisement, but we may add that the appointment will be made by the Treasurer of Guy's Hospital, by whom applications must be received not later than June 28th.

SIR FELIX SEMON, K.C.V.O., Physician Extraordinary to the King, is about to retire from practice, and a complimentary banquet is to be given him by his professional and other friends on Friday, July 2nd, at the Whitehall Rooms, Hotel Métropole. The organizers of the banquet are anxious to found a lectureship or scholarship in his name to be a record of his scientific work. Mr. Butlin will preside. All communications with regard to the Testimonial Fund, or applications for seats at the banquet, should be addressed to the Honorary Secretaries, Mr. A. Mond, M.P., 35, Lowndes Square, S.W.; Dr. P. Watson Williams, 4, Clifton Park, Bristol; and Mr. H. J. Davis, 8, Portman Street, London, W.

THE annual general meeting of members of the Research Defence Society will be held on Friday, June 25th, at the house of the Royal Society of Medicine, 20, Hanover Square, W., at 5 p.m. The Earl of Cromer, president, will take the chair and give an address. Other speakers will be Sir James Dewar, Sir Arthur Conan Doyle and Professor Starling.

Medical Notes in Parliament.

Visivisection.—The Home Office vote gave Mr. George Greenwood his opportunity of arraigning the administration of the Cruelty to Animals Act. He said the two inspectors under the Act received in all £895 a year. They did not give their whole time to the work of inspection, and he had nothing to say against them personally, but surely it was the duty of an inspector to try to find out any transgressions of the law, to detect and report them. Yet one of them said he was told by the senior inspector when he was appointed that he was not expected to act as a detective. This seemed to be telling him that he need not be efficient. The fact was both inspectors were pro-visivisectionists. In the year 1900 there were, under Certificate A, 8,954 experiments. This certificate allowed these experiments to be conducted without anaesthetics. They were generally inoculations; they might produce terrible suffering and terrible disease, but one would hardly expect the inspector to be present at them. Under the licence which allowed the experiment to be made under anaesthetics there were 1,113 experiments, while under Certificate B, which postponed the obligation to kill until the animal had emerged from the anaesthetic, until the object of the experiment was secured, there were 586 experiments. Then, under Certificate C, which allowed demonstrations to be given in vivisection for the instruction of students, the number was 181. The inspector for Ireland expressed a decided opinion, after many years' experience, that these were demoralizing certificates, and ought not to be granted at all. Take these licences under Certificates B and C. There were 1,885 experiments altogether, and of these the Chief Inspector, Sir James Russell, saw two. In 1905, under the licences in that year alone, there were 1,348 experiments; under Certificate B there were 1,013; under Certificate C, experiments for demonstration to students, there were 145; making a total of 2,506. The number of experiments under Certificate A—the experiments without anaesthetics, and, he supposed, without inoculation—had risen to the enormous figure of 35,429, but he did not count them in. Under Certificates B and C Sir James Russell saw 8 and Mr. Thane said he saw 15, or 23 in all out of 2,500—not 1 per cent. Under these circumstances what was called inspection under this Act was a farce, and almost a fraud. The public thought that these experiments were always subject to inspection. The evidence of the inspectors themselves showed that this inspection, so-called, was really a positive farce, and the public had been lulled into a false sense of security, as really the vivisector did what he liked, sent in his own report, and was never inspected by these officers. He protested against the manner in which the Act had been administered by the officials of the Home Office for the last thirty years. Applications for certificates were referred by the permanent officials to the Association for the Advancement of Medicine by Research—a private body formed for the promotion and protection of vivisection, and of which men might become members on payment of 10s. It was in evidence that the association was started "to bring effectual pressure to bear on officials." What it came to was this: the practice had been that the Home Secretary delegated the matter to the officials and the officials delegated it to the association. He next called attention to the returns presented to Parliament. For many years this return was presented to Parliament in a form which purported to distinguish between experiments which gave pain and painless experiments, but they never classed any under painful experiments, and it was supposed that all these experiments were painless experiments, or that they purported so to be. The return for 1905 came out in a different form, and there was no attempt to distinguish between painless and painful experiments, and he asked a question about it, and the answer was that the change was made because it was found impossible to make a separation between painful and painless experiments in some cases, and, it was impossible for any one—even the operator—to discover whether any pain was caused or not. That was a very significant admission, and he thought the change was hardly a change for the better. The Act of 1876 was passed for the prevention of cruelty to animals. The Act

was passed and came into existence because of the report of a Commission on which Professor Huxley sat in 1876. They found that there was cruelty, and they said:

It is not to be doubted that inhumanity may be found in persons of very high position, as physiologists. We trust your Majesty's Government and the Parliament of this Kingdom will recognize the claim of the lower animals to be treated with humane consideration.

The Act was passed, therefore, with this view, that the Home Office was to be interposed between the animals and the vivisectors, and the Home Office was to protect the animals: but speaking generally of the administration for the last thirty years, the officials of the Home Office had conceived it to be their duty to protect, not the animals but the vivisectors. There had never been any prosecution under this Act. In the first place, there could not be any prosecution without the consent of the Home Secretary; and secondly, there was no real inspection. One did not know what the inspectors reported. The report was that of the vivisectors, and these vivisectors were not going to give themselves away. They did so now and then, however; but this Act was under the six months limit provided by the Summary Jurisdiction Act, and they could not bring a prosecution after six months, and they never got the report until long after that period had expired after the experiment had taken place. Therefore it was impossible to institute any proceedings. He ventured to hope that in the future the right hon. gentleman might find it possible to administer this Act a little more for the protection of the animals, as the Act required, and a little less for the protection of the vivisectors. Mr. Akers Douglas, as an old Home Secretary, defended the administration of the Act. It had been administered, in his opinion, in so far as these operations went, with great humanity. The hon. member for Peterborough forgot to tell the House that very careful investigation was made into the character of those who had licences to carry out experiments on living animals by medical authorities. First of all, no operation could be carried out except in isolated places, and no experimenter could have a licence unless he was recommended by certain medical authorities, including the President of the College of Physicians or the President of the College of Surgeons. Therefore, he was hardly right in saying that care was not taken in the question of selecting those who carried out these operations. Sir William Collins said that, as a member of the Royal Commission on Vivisection, his lips at the present time were sealed; but he might say, in view of what had been said in debate, the Commission was now considering the evidence and preparing to issue a report. Mr. Gladstone, in his reply, referred to Mr. Greenwood's statement that when the inspectors went to the laboratories they would have a friendly chat with the operators and do nothing more. That conveyed a very serious charge, but he did not suggest for one moment that it was intended. Mr. Greenwood repudiated any such intention, and Mr. Gladstone went on to say that there was some danger in disputing about the principle of vivisection and the method of carrying out the law. Some might think vivisection was inhuman, and some might think it necessary in the interests of humanity. We had the Act, and it was of no use bandying charges of inhumanity against those who were appointed to administer that Act. He could quite understand that his hon. friend did not intend to say anything which might be construed as offensive to anybody, but it was his duty to stand up for professional men who were serving the Department and serving their country according to their own opinion and consciences, and who were faithfully discharging the duties entrusted to them. It was quite true that their whole time was not given to the work, but they were not paid for their whole time. They must have men who were competent for the work, and unless the Government was prepared to pay a very high salary it would never get officials who would be able to give their whole time to the work. All these were matters of administration by the inspector of the Department, and they came under review. Later on in the debate—after the London ambulance question, flogging, the condition of prisons, the alteration of sentences, the administration of the Aliens Acts, and other matters had been discussed in a thin house—Mr. Herbert Samuel, after Mr. Lupton had again raised the subject of vivisection, said that all these matters were

being thoroughly considered by a Royal Commission, which was now bringing its investigations to a close, and which would shortly present its report. As soon as its report was presented, it would receive the fullest consideration. In this consideration he might add, in reply to the hon. member for Lutonborough (Mr. G. Greenwood), who said that his right hon. friend delegated the work of issuing vivisection certificates to the Association for the Advancement of Medicine by Research, there was no foundation for that allegation at all. The Home Office had always investigated each case by the inspectors appointed by the Home Secretary, and it was on the report of those inspectors that the Home Secretary was satisfied or not satisfied as to the suitability of the persons who applied for licences. The debate then reverted to the administration of the Aliens Act, and on this subject a division was challenged, and the vote passed by 140 to 20.

Vivisection and London University.—Mr. George Greenwood asked the Secretary of State for the Home Department last week whether the words "University Physiological Laboratory" in the list of places on the Register under the Act 39 and 40 Vict., c. 77, in the Return of Experiments on Living Animals, No. 172, of June 11th, 1908, referred to the Physiological Laboratory of the University of London; whether that laboratory was now situate in the building which used to be known as the Imperial Institute; whether that building, or the part of it which was used for such laboratory, was purchased by public moneys; whether it was now owned by the State or by the university; and whether he would give directions that in future the returns of experiments on living animals should, in the list of registered places, set forth specifically the addresses of such places, in order that the public might be informed where such places actually were. Mr. Gladstone replied that the answer to the first and second parts of the question was in the affirmative. The answer to the third part was that the part of the building in the occupation of the University of London was transferred to His Majesty's Commissioners of Works under an agreement the nature of which was explained in Parliamentary Paper 300, July, 1899; to the fourth, that it was in the occupation of the university, and was held by the Commissioners of Works, as explained in the Parliamentary Paper just referred to. The return for 1908 was in print, but if his hon. friend would inform him of any reasons for giving more detailed addresses of registered places in future returns he would consider them. In the particular case to which he referred the address given was that used as the postal address of the institution. Mr. Greenwood then asked whether the university physiological laboratory was not in a building which was State property. Did it belong to the University of London or to the State? Mr. Gladstone said he could not say. He was not in a position to answer that question.

Death Certification.—Sir Walter Foster asked the President of the Local Government Board whether his attention had been called to the case of Mary Jane Walker, at Wolverhampton, who narrowly escaped premature burial owing to a medical man having given a certificate of death without having viewed the body; and whether he would take steps so to amend the law with regard to the certification of death as to render such dangers impossible in the future. Mr. Burns replied that he had seen a newspaper report of the proceedings at the inquest in this case. He was afraid he could not undertake to propose legislation on the subject of death certification during the present session.

Chloroform, Ether, and Drugs (New Duties).—Mr. Fell asked the Chancellor of the Exchequer what was the total amount of revenue which he anticipated he would raise from the new duties on chloroform, ether, and other drugs? Mr. Lloyd George said that he was not in a position to give any exact estimate of the revenue for the current financial year from the duties on these particular articles. The total net revenue during the last financial year was £2,127.

Newly-born Calves for Human Food.—In reply to Mr. Cathcart Wason, the President of the Local Government Board said that he could not state the number of newly-

born male calves butchered annually in the United Kingdom and Ireland. The carcass of a newly-born calf would usually be regarded as unfit for food, and would be liable to be dealt with by meat inspectors accordingly. If it was necessary to prevent danger arising to public health from the importation or preparation of these calves when intended for sale for human consumption, regulations could be made on the subject under the Public Health (Regulations as to Food) Act.

Military Camp Hospitals.—In reply to Mr. Joynson-Hicks, the Secretary of State for War said that the General Officer Commanding-in-Chief reported that 131 cases had been admitted during the present training period to Bulford Military Hospital, 261 to brigade and regimental hospital tents, and 39 to the military hospital at Tidworth. As regards the cases in the East Lancashire Division, 40 had been dealt with in hospital tents. None of these cases were reported to be traceable to preventable causes, such as inadequate supply of tent-boards and clothing. In reply to a further question by Mr. Joynson-Hicks, Mr. Haldane said that regulations provided for serious and dangerous cases being reported to the relatives of the patients, and a commanding officer must use his discretion in regard to other cases.

Army Hospital Blankets.—Mr. Ashley asked the Secretary of State for War whether the blankets of men admitted to hospital were used by other men without cleaning, for the unexpired portion of twelve months? Mr. Haldane replied that if the men admitted to hospital were suffering from any disease likely to convey infection the blankets were not used by other men without cleaning.

Cairo Water Supply.—In reply to Mr. John Robertson Sir Edward Grey said that the report of Sir Horace Pinching as to the quality of the water supplied from the wells of Rod-el-Farag was practically endorsed by the Commission appointed to examine the question, which pronounced that the water contained nothing detrimental to health (see BRITISH MEDICAL JOURNAL, May 8th, p. 1135). He was not aware what amount of money was spent upon the scheme, or whether any loss or danger had occurred through the use of the water, but the Egyptian Government had given practical proof of its desire to consult public opinion by the steps taken to examine the matter in consequence of the complaints which had reached them.

The Phthisis Death-rate in Greenock.—In answer to Mr. W. Thorne, Mr. Burns, replying for the Lord Advocate, said that the Local Government Board for Scotland were aware that the death-rate from phthisis in Greenock was somewhat high; they had the matter under consideration and were in communication with the local authority.

The Home Office Vote came on for consideration on Monday last, and Sir Charles Dilke opened the debate with a review of some points in the work of the year. He first of all dwelt on the excessive infant mortality in the towns where the mothers were engaged in work, and quoted from a report issued by the Bureau at Washington, which said of England, "Where mothers worked the majority of the children were dead; where they did not work the majority were alive." He said it was a disgrace that this could be said of some of our towns, and he hoped Parliament would never rest until it had met the evils of infant mortality. He then proceeded to give some gruesome instances of the maiming and death of small children working in factories, and urged a more strict enforcement of the law. He lastly referred to lead poisoning and the progress made in checking it by the Home Office, and said that manufacturers obviously had been trying to use this lead. He showed how this restriction had been beneficial, and called attention to the greater susceptibility of women to the poison. Mr. Gill, who followed, called special attention to the ill effects of dust on the lungs of the workers in the stripping and grinding trades. He said when it was found that 7 out of 10 of the men employed in this work were suffering from pulmonary diseases it was time something definite was done to remove this grievance, and it could be done at no very great cost.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

LONDON.

TREATMENT OF SCHOOL CHILDREN.

THE Hospital for Sick Children, Great Ormond Street, has notified the London County Council that it is willing to provide treatment at the hospital for twenty-five school children a week subject to the conditions that, as far as practicable, every child shall be accompanied by its parent, and that the cases attending on any one day shall be selected so as to avoid placing too great pressure on any one department of the hospital. It was suggested that the cases should be divided between the ophthalmic and aural departments.

The matter came before the Council on Tuesday, when the Education Committee, in recommending the acceptance of the offer, remarked that an experiment on this limited scale should prove valuable as a guide when the Council dealt with the general question. Acceptance would not involve the Council in any expense.

Dr. Beaton said he could not allow this report to go through without congratulating the Council on this great blow struck for the children of London. According to official reports 60,000 children needed treatment of the eyes, 15,000 of the ears, and 3,000 or 4,000 were suffering from ringworm. The Council has arranged with a hospital to treat twenty-five of these children for nothing! Nearly two years had elapsed since the question was first taken up, and now 25 children out of 80,000 were to be treated. Furthermore, 600,000 children had caries of the teeth, but their treatment was not even under the consideration of the Council. It was true that the Council recently determined in its generosity to spend £45 in treating suppurating ears, but none of the money had been spent at present.

Mr. E. G. Easton, a member of the Public Health Committee, in reply to Dr. Beaton, made an attack on the medical profession. Dr. Beaton, he said, should call to the bar of judgement the medical profession, which was responsible, to a very large extent, for the state of things he described. The condition of the children's eyes and ears was to be attributed to neglect by doctors and midwives during childbirth. Did Dr. Beaton suggest that the London County Council should make amends for the misdoings of the profession he adored? The medical profession were also responsible to some extent for the prevalence of bad dentition, having neglected to instruct their patients in the necessity of keeping their teeth clean.

Mr. A. J. Shephard said that Dr. Beaton's was a perfectly justifiable protest. He hoped this serious question would not be treated in the spirit of Mr. Easton's speech.

Mr. Cyril Jackson (Chairman of the Education Committee), replying to Dr. Beaton, said that this was the first offer from a hospital to come before the Council, but he hoped and believed there would be a great many more.

The offer of the hospital authorities was accepted with an expression of thanks.

INDIAN MEDICAL SERVICE.

The annual dinner in London of the Indian Medical Service was held at the Gaiety Restaurant on June 10th. The chair was taken by Surgeon-General G. Hay, in the absence of Sir George Birdwood, K.C.I.E., through ill health, and the guests were: General Sir O'Moore Creagh, V.C., K.C.B., Commander-in-Chief in India elect; Sir William Church, K.C.B., President of the Royal Society of Medicine; Mr. Henry Morris, President of the Royal College of Surgeons; Mr. Austin Low; and the Editors of the *Lancet* and the *BRITISH MEDICAL JOURNAL*. The officers present were:

Surgeon-Generals.—P. H. Benson, A. M. Branfoot, C.I.E., W. R. Browne, C.I.E., J. Cleghorn, C.S.I., J. P. Greaney, L. D. Spencer, P. W. Sutherland, B. Williamson.

Colonels.—W. E. Gates, D. E. Hughes, C. H. Joubert de la Ferté, H. G. L. Wortabet, W. A. S. Wynne.

Lieutenant-Colonels.—W. G. Alpin, N. L. Bartholomew, A. T. Bown, W. J. Buchanan, Sir R. H. Charles, K.C.V.O., A. Duncan, G. A. Emerson, P. J. Freyer, G. H. D. Gimlette, H. Herbert, R. A. K. Holmes, E. R. Johnson, D. F. Keegan, S. Little, C. C. Manifold, R. J. Marks, C. Monk, J. Moorhead,

J. O'Brien, A. Stephens, T. W. Stewart, A. W. F. Street, C. M. Thompson, W. H. Thornhill, D. Warlicker, G. Waters, A. H. Williams, F. W. Wright.

Major.—H. Bamfield, A. E. Berry, J. F. Blood, C. Bowle-Evans, W. S. Caldwell, C. F. Fearnside, J. Fisher, P. C. Gabbett, G. G. Giffard, C. H. James, A. J. Macnab, W. Selby, D.S.O.

G. B. Smith, F. W. Watling, C. G. Webster, E. H. Wright.

Captains.—W. R. Battye, F. F. Elwes, G. King, J. T. Leary, R. A. Lloyd, J. L. Lunham, J. H. Murray, W. S. Patton, A. E. H. Pinch, M. F. Reaney, W. S. J. Shaw, G. Tate, M. H. Thornely.

UNIVERSITY COLLEGE BAZAAR.

In order to find the £7,000 required to free the University College athletic ground at Perivale from debt, to make some necessary extensions, and to effect improvements, a bazaar is to be held on Thursday, Friday, and Saturday, July 1st, 2nd, and 3rd, at the college buildings in Gower Street. The wives and daughters of professors and other lady friends of the college have undertaken the management of twenty stalls. The students at the hospital and at the college have each their own stall, and the stall-holders are hoping to receive assistance in money or in kind from old members of the college. Lord Desborough has promised to assist the college generally, and, with Lord Howard de Walden, will arrange a fencing display. On one, and possibly on several, of the nights there will be a performance of Sheridan's *Critic*. Mrs. Roy will repeat the "Indian Tableaux" with which she recently delighted London. Episodes are to be portrayed from the life of Buddha, and Professor Gardner is arranging a series of Homeric scenes. An exhibition of pictures will be given by those members of the Slade school who have studied or taught there since Professor Brown has occupied the chair. Other side shows are to include demonstrations of the use of x rays and of liquid air by the medium of a "magic" kettle, dialogues by well-known artists, variety entertainments, and concerts. The Duke of Connaught has promised to open the bazaar on the first day. The Duchess of Sutherland will perform the same service on Friday, and Lady Reay on Saturday. Amongst patrons of the bazaar are His Royal Highness the Prince of Wales, the Duke of Connaught, and Lord Rosebery.

MANCHESTER AND DISTRICT.

THE HEALTH OF SALFORD.

THE annual report of the Medical Officer of Health for Salford estimates the population of the borough at 239,294; during 1908 the birth-rate was 29.8 per 1,000 and the death-rate 17.9. The number of stillbirths is put down at 270, but there is the usual uncertainty, as this only represents the records obtained from the registrars of cemeteries and sextons. The total deaths were 4,356, and of these more than a quarter were due to lung diseases, 849 being attributed to bronchitis, pneumonia, and pleurisy, and 383 to phthisis. Next in order come brain and nervous diseases 383, heart diseases 326, and diarrhoea 231. Of the zymotic diseases measles caused 168 deaths, and diphtheria 125, the latter being 39 above the decennial average.

Infantile Mortality.

There were 1,110 deaths of infants under 1 year of age, giving a rate of 15.3 per 1,000 births. This is an increase over 1907, when it was 140, but is still below the average of the preceding five years, which was 162. The death-rate among illegitimate infants, which numbered 231, was 290 per 1,000. The commonest causes of the infant mortality were bronchitis and pneumonia, which caused 186 deaths, atrophy and marasmus 182, diarrhoea 181, and premature birth 128. Compared with the eight Lancashire towns, Salford stands fourth on the list in infant mortality, the rates being Liverpool 142, Blackburn 150, Manchester 151, Salford 153, Preston 154, Oldham 160, Bolton 161, and Burnley 201 per 1,000 births. The infants specially visited and observed with the object of seeing the effect of various methods of feeding numbered 2,262; of these 85 per cent. were found to be breast-fed, and the death-rate among these was 97 per 1,000, only few of them suffering from diarrhoea. About 7 per cent. were fed on fresh cow's milk, with a death-rate of 284 per 1,000, diarrhoea being far commoner among these. It was also noticed that diarrhoea was far commoner when the

infants were given fresh cow's milk than when condensed milk was used.

Scarlet Fever.

There were 1,341 cases of scarlet fever notified, 403 above the average of the preceding five years, with 65 deaths, a mortality rate of 4.8 per cent. of the cases. About 76 per cent. of the cases were removed to the Ladywell Sanatorium. Ninety-six, or 7.2 per cent. of the total cases, were related to patients who had been returned to their home as convalescent after treatment in the sanatorium. The report says "there appears to have been a steady reduction of the number of carrier cases of infection of scarlet fever, which in 1903 was 13.2 per cent. of those discharged after complete desquamation, whereas in the present year it is 6 per cent., and desquamation is no longer taken into consideration in deciding the date of the patient's discharge." It ought not to be argued from this that desquamation has nothing to do with carrying of infection, for though desquamation is now neglected, much greater attention is given to seeing that there are no discharges from the throat and nose, and all that can properly be deduced is that such discharges are worse than desquamation, not that desquamation is harmless. Neither would any comparison with other towns, where desquamation is taken into account as it is in Manchester, be of any value, as other circumstances probably count for more; for instance, there is ground for believing that the use of convalescent wards before patients are discharged is of great importance, as probably there is both an intrinsic infection belonging to the patient, and an extrinsic infectious material inhaled by the patient from other cases, which lodges in the air passages. There is in fact no method of determining whether desquamation is infectious or not, except the discovery of the cause of the disease, and meantime Salford is running some risk in neglecting desquamation altogether.

Diphtheria.

Diphtheria has been unusually prevalent during the year, there having been 629 cases notified, against an average of only 387 for the preceding five years. The death-rate was 20 per cent. of the cases, the rate for the five years being 23 per cent. The attack-rate for Salford is consistently higher than in Manchester and Liverpool, and the medical officer cannot account for this, but the report says:

It is, perhaps, worth noting in connexion with this point that out of 513 notified cases sent into Ladywell Sanatorium by the practitioners of the borough, no less than 135 showed no clinical signs of the disease, and swabs taken from the fauces and nares gave negative results when examined for the Loeffler bacillus.

This implies rather than states a serious charge against the practitioners of the borough. It is acknowledged that a negative result in examination for the bacillus is not decisive, but patients believe that it means certain absence of diphtheria; and as somehow they often get to know the result of the examination, they jump to the conclusion that their medical attendant has made a mistake and sent them to a place where, if they have not already got diphtheria, they are pretty sure to get it. The statement that "no less than 135 cases showed no clinical signs of the disease" encourages this idea, and in simple justice to the medical men requires further investigation. At present the statement is received with some scepticism. The death-rate for cases removed to the sanatorium was 17.2 per cent., and of those treated at home 31.9 per cent., and the report suggests that this may be due to the lack of confidence in the efficacy of antitoxin among general practitioners. A singular fact has been the frequency of mixed infection of scarlet fever and diphtheria, which gave rise to great difficulty in the hospital. Towards the end of the year a routine practice was adopted of taking swabs from every scarlet fever case admitted, and 58 cases, or 9 per cent. of the total cases of diphtheria, were found to be connected with convalescents discharged from the hospital, many of whom had only suffered from scarlet fever. Comparing Salford with the rest of the country, the mortality-rates per 10,000 living were as follows: England and Wales 1, London 1, the seventy-six great towns 2, Salford 5. As the death-rate per cent. of the notified cases is about the same as elsewhere, it is evident that the true attack-rate is actually, as the notifications show, much higher in Salford than elsewhere, and this throws still further doubt

on the statement that so many cases notified showed no clinical signs of the disease. Vigorous measures should be taken to discover what local factors are at work in causing the large excess of cases in Salford.

Tuberculosis and Milk.

For phthisis a system of voluntary notification exists, and during the year 563 new cases were notified, of which 245 were visited by the health officers, and 318 were notified as "not to be visited." The most noticeable facts were the much greater incidence among males (362 cases) than among females (201 cases), and also the advanced age at which many cases commence, no less than 53 of the male cases having commenced after the age of 60. Also, among the male cases, 208 occurred among outdoor workers, and of these 131 were labourers and navvies; 84 samples of milk were examined during the year, and of these 13 were found to be tuberculous. Professor Delpine is engaged preparing a special report on the examination of milk for the presence of dirt, and so far, out of 72 samples examined, 11, or 15.3 per cent., were found to be distinctly dirty, containing 50 parts or over per 100,000 by volume.

Houses and Workshops.

Considerable work has been done in the inspection of insanitary property, lodging houses and workshops, and the report shows that Salford compares favourably in this respect with other towns.

THE MIDWIVES ACT IN SALFORD.

The information given in the annual report of the medical officer of health as to work done under the Midwives Act in Salford during 1908 is decidedly scanty and not altogether satisfactory. The total births during 1908 were 7,264, of which 5,541, or 76.3 per cent., were attended by midwives, and 1,723, or 23.7 per cent., by medical practitioners. These proportions are about the same as last year, and it is difficult to understand why in Manchester only 61 per cent. are attended by midwives, while in Salford over 76 per cent. are midwives' cases. There are fifty-two midwives on the Salford register, so that they average 106 cases each. As the medical practitioners number about 120, each attended only about 15 confinements in the year. During the year two midwives have been reported to the Central Midwives Board and have had their names removed from the roll. The total number of cases of puerperal fever notified during the year was 27, of which 8 died, giving a mortality-rate of 30 per cent. It is noted that 14 occurred in the practice of midwives and 13 in the practice of doctors. This is remarkable, as it works out at 1 case of puerperal fever in every 132 doctors' cases and only 1 in every 395 midwives' cases. This looks bad for the doctors, and the report is so incomplete that no explanation can be extracted from it. If only some particulars were given as to the time that elapsed between the confinement and the first symptoms of the disease, such as were given in the Manchester report for last year, it might be possible to tell how often the disease was caused by something occurring during labour, and how often by some carelessness on the part of the nurse after labour, as the incubation period is fairly well known. Statistics, however, about puerperal fever are extremely fallacious, and there can be little doubt that if a rise of temperature to 100.4° in the puerperium with quickening of pulse for over twenty-four hours is to be the test, far more cases of puerperal fever occur than are ever notified, and with a more careful supervision of midwives' cases by a medical inspector, probably more cases would be found than these statistics show. In any case, seeing that the remote results even of mild cases are often so serious, it is most important that the medical supervision should be as thorough as possible. The amount of chronic uterine disease in Salford is appalling, and there is little doubt that this is the result of former neglect of mild or overlooked cases of puerperal fever. The same may be said of cases of ruptured perineum. Before the Midwives Act came into force midwives took little or no notice of even extensive tears of the perineum. In 1906 the Salford midwives notified 19 cases, in 1907 36 cases, and in 1908 48 cases. This by no means shows greater neglect in the conduct of labour, but rather greater care in notifying the cases. But even now probably many cases of rupture are not notified as they ought to be, for it is found that while

the Salford midwives notify 1 case of rupture in every 115 cases of labour, in Manchester, where the midwives are equal, if not superior, in ability, and where the supervision is undoubtedly stricter, rupture was notified in 1 out of every 65 midwives' cases in the year 1907. Such a difference is too great to be attributed to anything except greater care in notifying in Manchester. A similar difference is seen in the total number of cases in which medical assistance is summoned. In Salford in 1907 medical aid was summoned by midwives in 1 case out of every 17 labours, and in 1908 in 1 out of every 14 labours. But in Manchester medical aid was summoned in 1 out of every 7.3 labours in 1907, the figures for 1908 not yet being available. Here, again, it is not that the Manchester midwives summon assistance where they ought to manage by themselves, as the conditions for summoning aid are strictly laid down and the supervision most careful; the reason is rather to be found in the imperfect provision for supervision in Salford, and, considering the large number of births attended by midwives in Salford, there would be ample work for a whole-time fully-qualified medical inspector of midwives in addition to the lady inspector, who would have quite enough work to do in other directions.

WEST YORKSHIRE.

DISTRICT MEDICAL OFFICERS OF HEALTH.

The West Riding County Council is at present considering the feasibility of appointing whole-time medical officers of health for combined areas in the county. In the rural districts and in the smaller towns the medical officers of health are at present general practitioners. It is proposed to combine two, three, or even four small areas and appoint whole-time officers. If security of tenure were only obtained for medical officers of health the difficulty of condemning insanitary property would soon disappear. Rather in this direction appears to lie the solution of the problem than in appointing whole-time officers at inadequate salaries.

ALLEGED INSANITARY HOUSES IN BRADFORD.

The owners of twenty-seven dwelling-houses in Bradford were summoned recently by the corporation to show cause why orders should not be made for the closing of the houses as dangerous or injurious to health and not reasonably capable of being made fit for habitation. The opinion of the Medical Officer of Health for Bradford (Dr. Arnold Evans) given in his evidence was that the properties were a nuisance and a danger to the health of the people living and working in the neighbourhood. The summonses were, however, dismissed by the bench, who considered that the prosecution had not succeeded in establishing the fact that the properties were not reasonably capable of being made fit for habitation. The Corporation will now no doubt try to compel the owners to put the property into a reasonable state of repair.

ANTHRAX IN THE WEST RIDING.

The centre of anthrax investigation in the West Riding has always been in Bradford. Formerly the late Dr. J. H. Bell took a profound interest in investigating and tracing the origin of the disease. His mantle has of recent years fallen on the shoulders of Dr. Eulich, and it is very gratifying to observe the recognition that is everywhere given to Dr. Eulich for his patient and laborious investigations into the causes of this preventable disease. In the annual report of the Chief Inspector of Factories for 1908 Dr. Eulich's methods, investigations, and conclusions are described in considerable detail, and these passages of the report will be found worthy of careful study. At the last meeting of the Anthrax Investigation Board Dr. Eulich reported that since the last meeting of the board, on April 19th, 2 cases of anthrax had occurred, both being external, and that one had proved fatal. A fatal case of this disease occurred at the Bingley Cottage Hospital on May 7th:

The patient was a man who pricked himself on the wrist with a sharp instrument in the course of his work a week previously. He was seen by Dr. Crocker, of Bingley, a day or two afterwards, who found a small pustule on the wrist. On May 3rd, and again on May 4th, a full dose of serum was given, and also periodical injections of carbolic acid. On May 5th the swelling of the arm had gone down considerably, and the patient seemed to be improving, but on the following day he became worse, and

was delirious. Dr. Eulich, who gave evidence, thought that the prick had introduced the bacillus directly into the blood, as the case was more severe than any he had previously seen. The post-mortem examination confirmed the diagnosis of the disease.

All the necessary precautions had been taken by the firm of woolcombers who employed the deceased, and the unfortunate loss of this man's life only shows the extreme difficulty of eliminating the danger of infection when the bacillus has at any time had the chance of infecting the material to be treated.

BIRMINGHAM.

THE GENERAL HOSPITAL.

On June 9th a memorial service was held in the chapel of the General Hospital for the late Miss M. E. Jones, who died on June 6th, and who was until quite recently matron of the hospital. In addition to the matron, assistant matron, house sister, and a large number of the resident staff of the hospital, there were present Sir John Holder, Bart. (Chairman of the House Committee), Mr. B. B. Tilley (Chairman of the Board), Dr. E. Malins, Dr. J. E. H. Sawyer, Mr. F. V. Milward, Mr. C. Woodward, Miss Mossop (Homoeopathic Hospital), Miss Armstrong (Moseley Hall), Miss de Chastelain (Jaffray Hospital), Miss Pidgeon (formerly matron of Jaffray Hospital), and the house governor (Mr. Howard Collins). The service was taken by the Rev. William Card, chaplain to the hospital.

The Lord Mayor (Alderman G. H. Kenrick) opened a large addition to the nurses' home on June 10th. This building, which has been erected to meet the demands of a growing staff of nurses, is especially designed for the night nurses. It is situated on the Wenman Row side of the hospital, forming a wing to the nurses' home, and comprises forty-three bedrooms, and a classroom for instruction in cookery for the sick. The cost of the new wing was about £8,000. A large number of ladies and gentlemen interested in the institution were present at the opening ceremony.

WALES.

THE WELSH MEDICAL DINNER.

The sixth Welsh medical dinner in London was held at the Criterion Restaurant on Tuesday, June 15th. The chair was taken by Dr. D. C. Lloyd Owen of Birmingham, and there was a large attendance. After the loyal toasts had been given from the chair, that of the "Prince of Wales" being followed by a most hearty singing of the anthem, the toast of Welsh men practising in all parts of the world and of medical men practising in Wales was given by Mr. Ellis Griffith, M.P., who dwelt on the distinguished position which so many Welsh practitioners had won for themselves in all parts of the world. The toast was acknowledged by Dr. Garrod Thomas of Newport. The toast of "The Visitors" was proposed from the chair and acknowledged by Mr. Henry Morris, President of the Royal College of Surgeons, and by Dr. Simon of Birmingham, who concluded by proposing the health of his friend the Chairman. The response of the Chairman brought the proceedings to a close. During the evening there was much excellent music, Miss Bessie Jones playing a harp solo and an encore, and Eos Dar intoning impromptus containing many topical allusions, more especially to the thirstiness of England which compelled it to go Wales for water; Miss Boddicombe also sang. The arrangements were admirably carried out by the Honorary Secretary, Mr. Howell Evans.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

RESIGNATION OF PROFESSOR OGSTON AND DR. ANGUS FRASER.

At a meeting of the Aberdeen University Court held on June 9th, a letter resigning the Chair of Surgery sent to the Court by Professor Ogston was read by the Secretary. Professor May, who was in the chair, said that by the

death of Professor Hamilton and the resignation of Professor Ogston, the Faculty had lost, perhaps, its two most widely-known members. Like Professor Hamilton, Professor Ogston was a man of the first rank as a teacher, and enjoys a cosmopolitan reputation as a surgeon and scientific worker. By common consent he was regarded as one of the two or three great Scottish surgeons of his time. Indeed, it would be difficult—apart from Lord Lister, who had some right to be considered as a Scottish surgeon—to name any other Scottish surgeon of the past thirty years who had done more for the advancement of surgery by scientific research. It added to the pride with which they regarded Professor Ogston that he was educated in that university. He begged to move that they should enter in their minutes an expression of their appreciation of the value of the eminent services which Professor Ogston had rendered to the university as a teacher and investigator of the highest order, and of their regret at his retirement.

The Chairman then referred to another great loss in the medical teaching staff associated with their university. After long years of most able service, their colleague, Dr. Angus Fraser, had retired from the Senior Physicianship of the Royal Infirmary, and with it from his position as one of the Lecturers in Clinical Medicine. There was no one whose great powers as a lecturer and clinical teacher have been more fully appreciated by his university colleagues, and by generation after generation of students, than Dr. Fraser. No one had endeavoured more fully to keep himself in touch with every modern advance relating to his subject, and although he had always been wholesomely sceptical and critical of merely new things, no one had been more ready to make use, for either diagnostic or curative purposes, of every well-ascertained discovery. Dr. Fraser had the personal magnetism of the born teacher, and none of his colleagues had had a stronger hold on the respect and affection of the students. The reconstruction and reorganization of the infirmary, by which their medical teaching had greatly benefited, was largely due to his initiative. Dr. David Littlejohn said he had special reason to know, perhaps, for a longer period than any of his colleagues at the table, both Dr. Ogston and Dr. Fraser, and had been acquainted with the most valuable services they had rendered. Dr. Ogston and Dr. Fraser he had known from boyhood, and they had in Aberdeen been very proud of them and of the position which they had attained and which they had held for so long. Those who were watching events closely, some five and twenty years ago, would remember that the Aberdeen Royal Infirmary had fallen behind externally and internally in the matter of what was looked upon as up-to-date requirements in hospital arrangements and management. Dr. Fraser and the late Dr. Robert Garden drew public attention very forcibly to what they viewed as being behind the times. Their action was strongly resented by the then management of the infirmary, and they practically imperilled their reputation and standing in Aberdeen upon making good the position which they had taken up. The result was that there was a complete reorganization and reconstruction of the Royal Infirmary.

LOCAL GOVERNMENT BOARD FOR SCOTLAND.

Mr. George M. Falconar Stewart, secretary to the Local Government Board for Scotland, has just retired under the age limit, and, on the recommendation of the Secretary for Scotland, the King has been pleased to appoint Mr. Abijah Murray, I.S.O., at present chief clerk, to be secretary, in succession to Mr. Falconar Stewart. Mr. Falconar Stewart joined the staff of the Board of Supervision (the earlier name of the Local Government Board for Scotland) in 1883, when he was appointed to undertake temporarily the duties of visiting officer. In 1885 he received a permanent appointment as visiting officer, and in 1897 he was made secretary. Mr. Murray joined the clerical staff of the Board of Supervision in 1873, and, after passing through the various grades, he was in 1897 appointed chief clerk.

PROFESSOR CHIENE OF EDINBURGH.

Professor John Chiene has placed his resignation of the Chair of Surgery in the University of Edinburgh, which he has held since 1882, in the hands of the University Court. At Christmas last he obtained leave of absence, but his health we regret to learn, has not improved

sufficiently to warrant him in resuming active work at the university.

EDINBURGH ROYAL INFIRMARY.

New Medical Out-patient Department.

The medical out-patient department of the Royal Infirmary of Edinburgh has been recast during the past year, many additions and alterations having been made. It is now in close proximity to the medical wards; there is a new large glass-covered porch or verandah under which an ambulance may be driven, and there is a large waiting-room (40 ft. by 36 ft. in size) and an isolation room with tiled walls for the reception of any suspected infectious cases. On either side of the waiting-room are suitable dressing-rooms with lavatories for male and female patients. These dressing-rooms communicate by two parallel corridors with a large demonstration or lecture room with raised benches and seats for eighty students. There is a separate entrance for students, a private room for the physicians, and a dark room for eye and throat examinations. Patients can leave without going through the waiting-room. A nurse's room, nurse's kitchen, and laboratory, have been constructed, opening directly off the main vestibule. Steam heated radiators warm the building, and an extract fan electrically driven is provided where special ventilation is needed. The walls of the various buildings are finished in polished Keene's cement, while in the waiting-room, vestibule, and corridors, there is a dado of glazed tiles. The floors in the waiting-room and corridors are of marble terrazzo, and in the dressing-rooms and demonstration rooms of red wood bedded in bitumen on concrete. The demonstration-room is lighted partly by means of three large windows in the end wall, and partly by a large roof light extending the full width of the room. The sanitation is in accordance with modern ideas. The cost has been £3,000, and the architect, Mr. A. Balfour Paul, of Edinburgh.

EDINBURGH ROYAL INFIRMARY RESIDENTS' CLUB.

The annual general meeting of members of this club will take place in the Caledonian Station Hotel on Friday next, at 7 p.m., when the Secretary's and the Treasurer's reports will be read. The fifteenth annual dinner will be held at 7.30 p.m., when Dr. Byrom Bramwell, president of the club, will occupy the chair. Members intending to be present must send their names to the Secretary, Dr. Edwin Bramwell, 24, Walker Street, Edinburgh, on or before June 21st. The treasurer of the club, Dr. W. Macrae Taylor, has prepared an interesting brochure, giving a history of the fourteen years' life of the club, its rules, a chronological list of events in the history of the residency, lists of presidents, secretaries, treasurers, etc., and a list of residents in the Royal Infirmary from 1837-8 to 1909.

PROFESSOR CLELAND.

The news that Professor Cleland had sent in his resignation of the Chair of Anatomy in the University of Glasgow is an entire surprise. For thirty years he has worthily upheld the traditions of the chair, and at the time of his resignation was, with the single exception of Professor Ferguson, the senior professor in the medical faculty; but in one sense Dr. Cleland was senior even to Professor Ferguson, as before he was appointed to Galway University in 1863 he had been senior assistant to Professor Allen Thomson. We are glad to say that Dr. Cleland's retirement is due to a desire for rest, and is not dictated by any special indication of failing health.

RUCHILL AGAIN.

A new life has been given to the unfortunate Ruchill episode by the wholly unexpected decision of the Town Council to accept and act upon a petition signed by 18,000 citizens. The petition, which has been promoted by the Woodside Municipal Association, is intended to restore confidence in the public mind as to the administration of the hospital. The terms of the petition are as follows:

We, the petitioners, respectfully call upon the Lord Provost, Magistrates, and Councillors to appoint an independent inquiry into the administration of Ruchill Hospital from the date of the Local Government Board inquiry up to the present date, and would suggest that the parties carrying out the said inquiry consist of our fellow citizens, drawn from the following bodies: Three from the Faculty of Physicians, three from the Faculty of Procurators, three from the Merchants' House, and three from the Trades Council, with a neutral chairman, such as Sir Donald MacAlister or Dr. Robert Gourlay.

This petition was adopted after discussion, and it was agreed that it be remitted to a special committee of the corporation to arrange for an inquiry. The corporation has shown a strange lack of consistency in their conduct of the movement for an independent investigation. As late as April 29th it decided by a large majority not to appoint a special committee of the town council to investigate the conduct of the Health Committee in regard to Ruchill. Yet within six weeks the council has completely turned round, and now has decided to hold an independent inquiry by outsiders, though in the meantime, so far as is known, no fresh reasons have cropped up for holding such an inquiry. It is to be hoped that if the inquiry takes place that it will be the final step in the interminable Ruchill dispute.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

CONOLLY NORMAN MEMORIAL FUND.

At a meeting of the subscribers to the Conolly Norman Memorial, held at the Royal College of Physicians, Dublin, on June 15th, under the Presidency of Dr. J. Magee Finny, Dr. Donelan submitted the secretary's report. It was found that the funds provided would not be sufficient to found an after-care association. The committee recommended that the memorial should take the form of a portrait of the late Dr. Norman, to be hung in the College of Physicians, of which he was President at the time of his death, and also of a bust in bronze with marble tablet, to be erected in St. Patrick's Cathedral. It was further resolved that the portrait should be painted by Miss S. C. Harrison and that the bust should be executed by Mr. E. Cairé.

PROFESSOR ALEX. FRASER.

We very much regret to learn that Professor Alex. Fraser, the distinguished professor of anatomy in the Royal College of Surgeons in Ireland, has been suffering for some weeks from the result of septic infection acquired during the preparation of a subject. He is able to be out of bed, and hopes to leave for Scotland very shortly to re-establish his health.

DOUBLE TENANCIES IN BELFAST.

In Section XII, or "Summary of Conclusions and Recommendations," of the Report of the Belfast Health Commission, we find in paragraph (7) of the portion entitled, "Sanitary Administration," the recommendation, "Double tenancy of houses should be prohibited, save where suitable water-closet accommodation is provided for each portion of the house let independently." This recommendation was generally approved. The miserable conditions indicated were a scandal and a shame to a civilized community; not merely were they unhealthy, but both morally and physically injurious. Under the influence of public opinion the Public Health Committee served notices on the landlords, and at the meeting of the committee on June 10th it was stated that landlords had given notice to the tenants rather than comply with the council's requirements, and it was affirmed that it was almost impossible to obtain other dwellings. By 6 votes to 4 it was decided to rescind the previous resolution as to the serving of the notices. A subcommittee was appointed to consider the question of erecting artisans' houses under the Housing of the Working Classes Act, in conjunction with the scheme at present under consideration dealing with the removal of insanitary dwelling-houses. The retrograde action of the committee has been condemned in the public press, as may be judged from the following quotations:

In view of the extent and terrible character of the evil which exists, and which the committee knows has existed for many years, it is difficult to find words sufficiently strong to condemn the action of the committee.

It is the sheerest nonsense to pretend there is not sufficient house accommodation.

The public health authorities have no right to favour slum landlords, who care nothing about the conditions under which their tenants live.

IRISH MEDICAL ASSOCIATION.

The annual meeting of the Irish Medical Association was held on June 15th in the Town Hall, Sligo.

The President, Dr. E. C. MacDowel, in his opening address, said no doubt the reason Sligo was chosen as the seat of the conference was that the Sligo Branch had succeeded in getting a graded scale of salaries adopted in the Sligo Union. Some 50 out of 159 unions had adopted the scale, and some 400 dispensary medical officers had benefited accordingly. This was a result of which the Irish Medical Association might be proud. He would like to be able to speak more hopefully as to the future prospects of superannuation, but under the present régime a life of grinding toil, of self-sacrificing devotion to duty, would not gain this reward unless the medical officer was able somehow or other to conciliate his masters. Last October Dr. Rawson, of Carlow, the Medical Officer of Carlow Union, was refused superannuation after twenty-six years' meritorious service. He had since been granted a miserable pittance of £30 per annum. The Castlereagh Guardians also recently refused superannuation to their aged doctor, now gone to his long rest. It was humiliating in the extreme that doctors should be subjected to such cruel injustice. Referring to the recommendations of the Viceregal Commission, Dr. MacDowel expressed the hope that the Legislature would not repeat the errors of 1838 and foist on the country a Poor Law authority under a new title. The Poor Law system was always detested by the Irish people ever since it was introduced; it treated poverty as if it were a crime; and, notwithstanding certain alleviations, the dislike still continued. The report of the Viceregal Commission was a most able and exhaustive document, and a really statesmanlike effort of three distinguished Irishmen to deal with the reform of the Irish Poor Laws. There was an absolute unanimity of opinion throughout the Poor Law Medical Service that the Public Health Administration had been an utter failure. This breakdown had been most marked in the small towns and rural districts, the sanitary condition of many of these being deplorable. The sanitary laws, taking them all round, were excellent; the failure was due to the fact that they were very rarely administered with firmness. The failure could not be laid at the door of the medical profession. No more faithful servants ever existed than the Poor Law medical officers of Ireland. The blame was to be attributed to the obsolete, ineffective system; and the initial mistake occurred when the Public Health Act of 1876 made every Poor Law medical officer *ex officio* a medical officer of health. The onerous duties placed on them were only rewarded with a nominal salary of the most miserable description, and it was not to be wondered that the new responsibilities were often evaded. The next and most fatal error was in the constitution of the so-called sanitary authority. These bodies, which knew little of the A.B.C. of sanitation, were the practical masters of medical officers. The medical officer had to report to this body, which could carry out his suggestions as it thought fit, and very often his valuable report was consigned to the waste-paper basket. There was an urgent need for a Minister of Public Health, and the creation of a strong central medical board vested with sufficient powers to influence all medical legislation for good, and presided over by the Minister of Health. The question of a State medical service, and the cost thereof, to be defrayed out of money voted by Parliament, was of enormous importance. The formation of such a service would greatly raise the prestige of the profession, and ensure the election of medical officers on merit, and not on political or religious grounds. It was notorious that in the elections there was much bribery and corruption, and such practices were on the increase. Referring to Sligo, the President said the less said about its sanitary condition the better. The streets were badly kept, there was a very imperfect system of scavenging, and the poor dwelt in many instances in foul alleys. The Infectious Diseases Act was not in force, the town had no public ambulance, no baths, while means of disinfection were often ludicrously ineffective, and the results were deplorable.

THE APOTHECARIES' HALL.

On June 11th the members of the Apothecaries' Hall, Dublin, presented the Governor, Dr. Seymour Strutch, with a service of plate on the occasion of his marriage. The presentation was made on behalf of the subscribers by Colonel Adye Curran, M.D., F.R.C.S., who said that though the Hall was founded by the Irish Parliament in 1791, it

was the first occasion on which the governor had been married during his year of office. Dr. Stritch acknowledged the testimonial in a suitable speech.

CORK MEDICAL AND SURGICAL SOCIETY.

At the recent annual meeting of the Cork Medical and Surgical Society the following officers were elected for the session 1909-10: President, Professor D. T. Barry; Vice-President, Dr. J. Booth; Honorary Treasurer, Dr. C. B. Pearson; Honorary Librarian, Dr. E. Murphy; Secretary, Dr. J. T. O'Connor. A Council of seven members was also appointed.

WAR IN CASTLEREA.

Though we have not referred to the proceedings of the Castlereah Board of Guardians for some months, it must not be supposed that this celebrated board has been idle during that period or failed to provide a weekly supply of entertainment for the Irish community. Indeed, it has been going stronger than ever, but as we foresaw a climax was impending we thought it better to defer further reports until it occurred.

At the risk of wearying our readers we must, however, recapitulate in brief the contest of this board with their medical officers and the Local Government Board.

Castlereah is a large union hitherto divided into four dispensary districts, and included in it are a number of small towns. About two years ago the four medical officers applied to the guardians for a graded scale of salaries as in other unions, assigning as their reason that their salaries of £100 a year each were insufficient to provide for the bare cost of locomotion in their very large districts. The guardians, after sundry facetious comments, consigned their application to the waste-paper basket, and a similar application, made a few months later, met with a similar fate.

Then the medical officers applied to the Local Government Board, and that body sent the guardians a mild remonstrance and a request for a reconsideration of the matter, followed, so far as the guardians were concerned, by a repetition of the facetiousness and a further recourse to the waste-paper basket. A further remonstrance in stronger terms had the same result.

Next the Local Government Board sent down an inspector to hold a sworn inquiry. The doctors gave evidence as to the vast areas they had to cover in the discharge of their duties, one district being eighteen miles from end to end; some of the guardians also gave evidence. Those who lived far from a doctor thought they should have one next door, and those who had a doctor close at hand thought four medical officers quite enough for the poor of the union. Of course, it was always the "poor of the union" they were anxious about, but, as was to be expected from arithmetical considerations, the majority wanted more doctors—not for their own convenience, only for the poor. So the Local Government Board invited them to frame a scheme for dividing the union into five districts with five medical officers.

Our readers can imagine the wrangle that ensued. Every time a resolution was carried a notice of motion was given to rescind it, and so the game went on for months, until the Local Government Board walked in with a sealed order rearranging the union into five districts as it thought most suitable.

It was then that all the blood of their heroic ancestors flew to the guardians' heads. "Resolutions and counter resolutions to be sent to the local M.P.s, the Chief Secretary, and others," were passed or recommended on alternate weeks protesting against this further injustice to Ireland, but all to no purpose. The Local Government Board refused to budge.

The next step was that the guardians instructed their solicitor to apply for a writ of *quo warranto* to set aside the sealed order as being *ultra vires*. It came before a judge of the High Court in due time, and was promptly decided against the guardians. It was a severe blow to their patriotism. They did not go so far as to say the judge had been bribed, which was rather surprising, but after a tremendous fight amongst themselves they decided to appeal. The appeal was dismissed with some £600 costs, and we believe it was this £600 saved the unfortunate ratepayers of Castlereah from an appeal to the House of Lords, for defeat there would have been disastrous.

The Local Government Board having ordered the guardians to advertise for two medical officers for the two new districts created by their order, they had no choice, but they overreached themselves by inserting an illegal condition. They advertised for two medical officers at a salary of £100 a year each, imposing a condition that they should attend "poor persons," a most elastic term in Ireland, at ridiculously low fees when distances are considered. The election took place, and the result is seen in the following letters:

Local Government Board, Dublin,
May 7th, 1909.

Sir.—The Local Government Board transmit herewith, for the information of the board of guardians of Castlereah Union, a copy of a letter which they have received from Dr. J. W. Beirne, complaining that at the election held on the 17th ult. to appoint medical officers for the Ballaghadereen and Loughglenn districts, the guardians endeavoured to impose upon the candidates, as a condition of appointment, that the person appointed would attend private patients upon a special scale of fees fixed by the board of guardians. Dr. Beirne states that the candidates, when the matter was brought under their notice, held a conference, and arrived at the unanimous conclusion not to consent to the suggested scale of fees, and signed a document to that effect; but that subsequently some of the candidates, notwithstanding this undertaking, notified their acceptance of the scale of fees. In the circumstances Dr. Beirne states he refused to allow his name to go forward to the poll for the medical officer of Ballaghadereen district as a protest against the proceedings. The Local Government Board have Dr. J. W. Beirne's letter, and consider that the scale of fees should be arranged under Article 7 of the dispensary rules, guardians are not authorized by law to require candidates for the office of medical officer of a dispensary district to agree to accept a fixed scale of fees for attendance upon private patients, and they have endeavoured to intimate that the manner in which the election was conducted by the guardians on the 17th ult. was such that the Local Government Board, in the exercise of their discretion, consider that they should not approve of the appointment made if the facts are as stated in Dr. Beirne's letter, but that a fresh election should be held.—I am, etc.,

A. R. BARLAS, Secretary.

(Copy of letter.)

Ballaghadereen, April 19th, 1909.

Sir.—An election for the appointment of medical officers for the Ballaghadereen and Loughglenn Dispensary Districts was advertised to take place on Saturday last, April 17th, at Castlereah, and in accordance with the advertisement was a candidate for the Ballaghadereen vacancy, and having made my application I attended on Saturday last the meeting of the board at which the election was to take place. When the motion for the election came on there was a proposal moved of a scale of fees, no mention of which was made directly or indirectly in the advertisement for the appointment, and naturally I felt constrained to object to the procedure on principle. Some councillors moved that the candidates for the I was to should consult amongst themselves as to the advisability of agreeing as to this new element of the scale of fees being introduced into the appointment and therefore allow the election to proceed. The candidates accordingly held a consultation, and came to the unanimous conclusion that they would not consent to it, and signed a document stating that they would not agree to the scale of fees being introduced then. After this document was signed and handed in before the board, some of the candidates changed their minds, and, I presume, acting on the suggestion of their friends, or for some other reason, made up their minds to sign a document accepting scale of fees, and the election being proceeded with. I refused to allow my name to go forward, as a protest against the irregularity and illegality of the whole proceedings. I now formally protest against the action taken, and ask the Board to refuse to sanction the election, and request that a new election be ordered.

(Signed) J. W. BEIRNE,
Acting M.O., Ballaghadereen.

In the apportioning of the new dispensary districts the town of Castlereah was taken from Dr. Donnellan, who had been the leader of the insurrection, was the oldest medical officer, and had the largest district in the union, and given to Dr. O'Donoghue, who held an adjoining district, but the Local Government Board decided most justly that Dr. Donnellan, who had over twenty years' service, should not be required to leave the town of Castlereah to reside in another part of his district, and they also advised the guardians that Dr. Donnellan was entitled to reasonable compensation for the loss of registration and vaccination fees, also for the loss of the most easily worked portion of his district, and that Dr. O'Donoghue was entitled to have his salary increased on account of the extra work thrown upon him. "A further attempt to rob the poor ratepayers by the minions of an alien Government" was about the mildest comment upon these suggestions as they were

consigned to the waste-paper basket, which by now must be pretty full. Having afforded the guardians full time for consideration without any effect, the Local Government Board have sent them a sealed order, fixing Dr. Donellan's salary at £140 per annum and Dr. O'Donoghue's at £122—certainly a most inadequate recompense in the case of a man who like Dr. Donellan has devoted his life to the work.

We should be sorry to assert that Castlereagh is a specimen of all other Irish boards of guardians; but there is far too much of this sort of senseless extravagance going on to the detriment of the interests of the ratepayers, and we think that the extended powers for the Local Government Board asked for by that able administrator Mr. John Burns would be an incalculable benefit to Ireland. A large extension of the powers of that Board would make for efficiency and economy impossible under the present system. That the people realize this was shown by their unanimous approval of the proposals of the Viceregal Commissioners.

Special Correspondence.

BERLIN.

House Disinfection after Tuberculosis.—Portable Field Cooking Apparatus.—Treatment of Inebriates.

THE magistrates of Wilmersdorf, a large suburb of Berlin, have determined to carry out, free of charge, the disinfection of all homes in their district from which a tuberculous person or persons may have removed. It will be interesting to see how this measure, which was much discussed and warmly advocated at the recent Congress for Tuberculosis, and has been in force for some time in other countries, will work in Germany.

The Berlin branch of the German "Vaterländische Frauenverein" recently invited experts to witness the practice of a special ambulance detachment, and to test a new transportable camp-kitchen for army purposes. This kitchen, which was constructed by the Senking Works in Hildesheim at the suggestion of the Prussian War Ministry, consists of a boiler for 200 litres of food, and a coffee-boller for 50 litres, both of which can be expeditiously heated in an oil-bath, thus avoiding freezing of the water, which is the great danger of the ordinary water bath (*bain-marie*) cooking. The boilers are made of pure nickel, to prevent oxidation of the food, which remains good for thirty-six hours without any replenishment of the fire, and which can even be kept for three or four days without turning sour, if the boiler-temperature does not fall below 40° C. The whole apparatus is most simple, and can be managed without previous instruction. Directions for use are fixed in a prominent place. The price is from 4,500 to 5,000 marks, that is, £225 to £250.

In a petition lately presented to the Prussian Diet, the Association of German Inebriate Asylums prays for more efficient legislation in the care of habitual drunkards. It appears that there are at present in Germany thirty-one charitable establishments for the care of inebriates, with 1,137 beds in all, and that during the year 1907 1,500 persons (of whom 188 had previously been interdicted) were received as inmates. At the close of 1907 there were 761 beds occupied. If these small numbers be compared with the thousands of dipsomaniacs who, year out year in, crowd German general hospitals and lunatic asylums; if the enormous sums these miserable victims of alcoholism cost the State and the municipalities be remembered, then every one must agree with the petitioners that stricter, and above all more practical, measures are required than the present method of interdiction preceding forced seclusion. In Germany hardly more than a thousand persons are annually put under trustees, the reason not being far to seek. Besides the difficulty of finding a "disinterested party" among the near relations, the dipsomaniac's family is deterred from applying for his interdiction sometimes by false shame or want of energy, and often by fear of his brutalities, or by apprehension of the expense. The Poor Law guardians, too, dread the trouble and costs of the present complicated procedure, and so things continue to go on in the old unsatisfactory manner, though the evil is known and acknowledged.

Correspondence.

SPEECH FRIGHT.

SIR,—I love to see a letter from Dr. Farquharson! It is sure to be out of the beaten tract—something original, something interesting. But I suppose that when he was a hospital physician he used to write like the rest of us, saying that the temperature was high or the appetite bad. (You, Mr. Editor, know the style.) However, I am not alluding to-day to written articles and reports, but to speeches.

One of the finest speeches which I have ever read was Lord Rosebery's of the other day to the press delegates. I wish that I had heard it! And as I read it I said to myself, "And this great orator once lost his thread in the House of Lords." And the thought gave me great comfort. Rosebery, the greatest and most graceful of our speakers, "drying up," as the actors say.

"After the Lord Mayor's carriage comes the dust cart." Sometimes I make a speech. I never seek to make one. I always back out of it if I can. But every man has a certain amount of duty which he must not shirk, and now and then I feel bound to accept the invitation to make a speech. And from the moment that I have accepted a cloud hangs over me! When I wake in the morning I say to myself, "In three days I have to make that speech," and the same thing occurs with increasing frequency as the time approaches. As the days pass by I get together some rough ideas and dot them down on a piece of paper. Then I get the words into sentences, and polish them up as best I can. It is probably an after-dinner speech; and at the dinner I am miserable. When the soup is put before me I want to stand up and deliver myself. But I must not. As the dinner goes on every one around me seems to be quite happy; I am miserable. At last the Toastmaster calls out, "Pray silence for your Chairman"; and then I feel inclined to sink off and never return. But I can't. I have undertaken to make a speech, and I must needs see it through. But my time is not yet. There are other speeches before mine, and songs or recitations, all of which prolong my misery! My neighbour at the table says, "I see you are down for a speech." I reply, "Yes, I am sorry to say that I am." He rejoins, "You? Why it is nothing for you to make a speech; you are first-rate at it." He is kind and flattering, but he doesn't know. As a matter of fact, I am miserable. My heart-rate is becoming excessive, and I am breaking out into a profuse perspiration. My hands are clammy, and I am more miserable than ever. Then my turn comes, and I give a sigh of relief, much as, I suppose, the criminal does when he descends from the dock to do his time.

Somehow or other, I have always up to this got through the task without failure, but I am always more disappointed with the result than my kind friends seem to be. I am thankful that I have not failed; thankful to be safely delivered. And in my thankfulness I am quite humble, and I say to myself that on the next occasion my speech will certainly be a "frost"—that it is only a question of time when a speaker comes to grief. For even the very best sometimes fail.

After my delivery I am less miserable than I was; but I am anxious to get home. "I am afraid to think on what I've done; look on't again, I dare not!" But I cannot get away from it, and on my way home I remember the "points" which ought to have been made. My evening has been made miserable, and peace comes only with sleep.

I wish that Dr. Farquharson would ask Lord Rosebery to read the correspondence on this subject and induce him to write a few lines for our JOURNAL. We know that his speech is not like the song of the skylark, "unmediated art," but his art is perfect; it is absolutely concealed. Would that he might tell us how he goes to work!—I am, etc.,

June 12th.

CELT.

SIR.—Undoubtedly there is a great deal more in the etiology of this condition than one can perceive at a cursory glance, and is of more importance than a passing notice would lead us to believe; the intricate nervous

metabolic changes which take place whether they be of a functional nature or otherwise, are most difficult to understand, and, from my experience, they occur in several members of a family and in various degrees, and are hereditary. I have a case in my mind's eye now, which to me demonstrates that the "causa causans" is in the commissures between the primary intellectual centres (glossokinaesthetic) and the motor speech centre.

This individual as a boy stammered, and while he was perfectly conscious of what he wanted to say, was at a loss to convey his meaning owing to his speech centre, or the commissures between the glossokinaesthetic centre on the floor of the fourth ventricle being in some way temporarily aberrated, and this was in all cases intensified during excitement, or when suddenly taken to task, at the same time several other nervous conditions exhibit themselves, such as tremors, twitchings, and jerking movements of the different parts of the body. When speaking quietly and dispassionately language came fairly fluent. As the youth grew older the stammering ceased, or nearly so, and another condition developed, apparently in its stead and evidently closely connected with it, for when under any excitement or undergoing some unusual ordeal, such as being presented to some important personage, or suddenly asked to take part in a discussion, speech seemed suddenly to leave him, or, as it is usually said, "his tongue clove to the roof of his mouth," and often only a few muttered, incoherent sentences could be made; at other times, if suddenly spoken to, while conscious of everything and thoroughly conversant with the details in question, and conversation could be carried on fairly well, some part of the intellectual faculties seemed to be in abeyance—memory seems momentarily to fail—he could not recollect the names of persons and technical things under discussion, which at other times were quite familiar, and in his quiet moments he would be able to write a perfect paper upon the same subject in lucid style without any reference or loss of memory.

I think all this goes to show that the fault lies in the communicating nerve tracts of the brain itself—that is, in the commissures linking up the various intellectual centres with the speech centre—and not the centres themselves from some cause being over-stimulated and fail to act at all. And these commissures are probably put out of gear by some other condition, perhaps, causing momentary stasis or engorgement of the blood in the capillaries surrounding these tracts, involving the motor fibres, too, as tremors, nervous twitching movements, and suchlike frequently accompany and are often observed to be associated with the affection, though I am aware this is contrary to the physiological teaching relative to the cerebral circulation. And anything which could prevent this occurring would, to my mind, abolish or mitigate the distressing condition. In the particular case under discussion a cup of hot tea or coffee—tea especially—had a remarkable effect in calming down and reducing the uneasiness, whether taken alone or after a meal; but the degree of mental disturbance was always much exacerbated when for some hours no food had been taken.—I am, etc.,

Birmingham, June 13th.

CLEMENS BELCHER.

SIR,—Although the following note scarcely comes under the heading of "Speech fright," yet it has been recalled to mind by this correspondence and may, perhaps, interest your readers, as it illustrates what is probably a little known therapeutic action of repeated small doses of opium.

Many years ago in India I heard an officer relate his experience during the Afghan campaign. He had occupied an important staff appointment, the duties of which were extremely heavy, entailing much worry, responsibility, and night duty. He was rapidly breaking down, both mentally and physically, under the strain, when one of his native officers strongly urged him to take grass of opium every morning before he commenced work. The remedy was tried, more from curiosity than from anything else. In a week or ten days all the unpleasant symptoms had disappeared; lapses of memory seemed almost impossible, and he went through the rest of the campaign without strain or difficulty. He felt convinced that the use of opium had saved him from a complete breakdown, if not from actual insanity.

The difficulty came later on when the strain was over

and it was necessary to give up the drug. This was only accomplished by stern determination, after months of considerable suffering.—I am, etc.,

June 15th.

G. H. YOUNGE,
Lieutenant-Colonel, R.A.M.C. (ret.).

SIR,—I am particularly interested in the suggestion made by several correspondents to use opium in some form in the treatment of this condition; for it corroborates a little experience of my own in 1895. This occurred at a picnic to which I had been invited by a brother medico. For some reason, which I cannot now recollect, I took 1 dram of liquor morphinae just before starting. I am by nature of a very retiring disposition, shrinking from all social gatherings, dances, picnics, and the like; in fact I cannot remember ever having really enjoyed one in my life. But, on this particular occasion, all reserve seemed blown to the winds; I was full of go, up to all sorts of pranks and fun; in fact, my host, who had known me for years as a steady, inoffensive young fellow, perhaps a trifle dull, said he never suspected I had as much go in me. Personally, I may say that it is the only occasion upon which I ever fairly "let myself go," and, moreover, I had no unpleasant after-effects, not even a breach of promise action which might quite reasonably have been expected. Warned by medical friends, to whom I have related my experience, I have avoided repeating the experiment, and so, like Oliver Wendell Holmes's funny man, I may say—

Albeit in a general way
I am a sober man,
Since then I never dared to be
As funny as I can.

—I am, etc.,

June 15th.

H. E. B.

SCHOOL CHILDREN AND THE HOSPITALS.

SIR,—Dr. Sidney Phillips's failure to appreciate the point of view expressed in the circular on the above subject issued by the Metropolitan Counties Branch Council seems to be due to a misapprehension on his part as to existing conditions. In his letter he three times refers to "the school doctor." But the whole point of the trouble is that there is no school doctor, and that a proposal is being made that the County Council shall remedy this defect by inducing the honorary outpatient officers of the voluntary hospitals to fulfil the functions of this missing official. There are of course medical inspectors of school children, who are not permitted to carry out any sort of treatment; but these cannot be the officers that Dr. Phillips refers to as school doctors, and with whom he intimates that the staff of the outpatient department might co-operate as consultants. One could no more act as consultant to a medical inspector debarred from practice than to a relieving officer without a medical qualification.

I am confident that it is but necessary to point out to Dr. Phillips this error into which he has fallen to ensure that he will reconsider his attitude on this question. It is important that the profession should stand together in resisting the proposals that are being put forward by the County Council or by others on its behalf. When the County Council has made arrangements to ensure that all children found needing treatment in their schools shall secure treatment at the hands of medical practitioners who are properly remunerated for their services, either by the child's parent, or by the Council, or by the guardians of the poor or by the charitable public, or by the friendly societies, or, indeed, by anybody, provided only that they are properly remunerated—then, but not before, it will be possible for the voluntary hospitals to consider the terms on which they can reasonably ask the members of the medical staff to co-operate in the treatment of these children.—I am, etc.,

June 14th.

LAURISTON E. SHAW.

SIR,—Dr. Phillips in his sentence, "That a child eligible for treatment forfeits its right to it if its qualification is detected by the State—that is the London County Council," exactly hits the nail on the head. If the State or the London County Council wish to provide medical aid for a child let them pay market price for it.

By all means let the State or the London County Council find out if a parent is doing his duty by his child. Having found out that he is not so doing, let them notify him as to his liability, and see that he accepts it.

The existing law is quite strong enough to enforce proper care of children, and the arrangements of the Poor Law and charitable institutions are able to afford all the relief necessary, if the parent cannot pay the necessary fees.

The owner of the land on which schools are built has not of late years given the ground for them; the architect who drew the plans, the contractor and workmen who built them, the teachers who work in them are all paid for their services. Why should the doctor, who attends to the ailments of the children, be the only person who is not paid a proper fee?—I am, etc.,

Bradford-on-Avon, June 14th.

HERBERT P. TAYLER.

"THE DOCTOR AS A VICARIOUS PHIL- ANTHROPIST."

SIR,—I do not know whether you feel obliged to print every letter sent to you or not; but if you do I am sure you must have been as sorry to print as I was to read that from Dr. Wishart Kerr.

Men who act as he did are simply lowering the status of the profession to that of a trade, and that even not of a good trade.

Any shopkeeper seeing a small boy in serious want of food would have willingly given it to him. Most good tradesmen do not require payment before supplying one with goods; but when a poor child has been hurt in an accident, and has been brought to our surgery, we have no right to refuse first aid without payment. We may have the right to refuse to continue the treatment of the case, but the present suffering should be relieved; and Dr. Kerr's refusal to treat the poor child was a disgrace to the profession which he vaunts himself he is upholding. —I am, etc.,

Grange over-Sands, June 7th.

OWEN GWATKIN.

SIR,—The letters under this heading must have appealed to all of us and recalled sad memories of time and trouble freely given—alas, too freely. It is a real grievance which the profession has to endure: for not only has the case to be dealt with, but subsequent treatment is also thrust upon one, lest, for instance, a badly united fracture should be ascribed to his improper setting. It produces strange results. For instance, one man I know now poses as a doctor indeed, but of music, when attending, as is his wont, numerous race meetings. He found his little jaunts too frequently disturbed by being called to accidents on the course, which never resulted in anything more than thanks. The climax came when, after attending an aristocratic gentleman rider in a bad accident in the first race and losing his day's amusement and his day's expenses, his little bill was ignored. The work, too, is not pleasant. For instance, after examining as far as practicable an injury to the hip in which one suspects an impacted fracture, it is difficult to answer the numerous inquiries of "Is it broken, doctor?" (such a simple question, too) in a manner that will redound to his after-credit. I have often hoped to meet one British citizen who would exercise charity out of his own pocket in a case of emergency instead of, as now, at the expense of the "noble profession."

The fact is we are too noble and too unbusinesslike, and, considering how many general practitioners can now barely make both ends meet, the time has come to make a stand against the burdens placed upon us. For instance, the petrol tax; we should all take care, by strictly charging mileage and being firm with our country patients, that the tax is paid, not by us, but by the public. Again, does the present state of affairs help the public? No doubt there are many who, like myself, lacking Dr. Kerr's courage, evade the difficulty by issuing orders, "Not at home to accidents." In the end the public get what they pay for (with only about 100 per cent. thrown in), as in the case of club practice where, unwisely for themselves, the best class of working men have cut down fees to a point which compels a corresponding cutting down of visits and drugs. A most exacting profession should at least allow

its slaves to be freed from sordid pecuniary worries. We have a monopoly; why not use it? I enclose my card, but fearing local opinion, can only remain

June 7th.

NOT AT HOME TO ACCIDENTS.

RURAL DISTRICT NURSING ASSOCIATIONS.

SIR,—Several letters have appeared lately in the BRITISH MEDICAL JOURNAL with reference to district nurses.

May I give my experience of the Belvoir District Nursing Association? This exists to supply nurses to its members, chiefly of the working agricultural type, in this neighbourhood.

The nurses are resident—that is to say, they are sent from the central home to a particular case, and when this is finished they return to the home. In the patient's house they are expected to nurse the patient, cook, and generally look after the welfare of the house and carry out the doctor's orders.

They are clean, respectable women, able to take temperatures, etc., and not above their work. They are not allowed to meddle with other patients than their own, nor to prescribe. They are under complete control. They fill a distinct want, and are acceptable to both their patients and to the doctors.

The advantages of such a system to the district nurse depicted in your columns who is dumped down in a locality to prescribe, nurse, interfere without let or hindrance is obvious. I commend it to the consideration of those who have to form or reform rural nursing associations.—I am, etc.,

Nottingham, June 7th.

W. WINDLEY.

THE CAUSATION OF CANCER.

SIR,—I understand from Mr. Marsden's letter that he considers that chronic irritation upsets the normal equilibrium between, say, the epiblast and mesoblast, so that, if I may coin a word, the "tissue-tension" of the one exceeds that of the other, and an invasion results. One can adduce some support for this in the fact that sarcoma is commoner in youth and epithelioma in advanced age. In youth the mesoblastic tissues are at the height of their activity, but the need for surface protection and sensation is not vastly greater than in later life. Here, then, the tissue-tension of the mesoblast will tend to exceed that of the epiblast and hypoblast—hence, sarcoma following a special call upon the reproductive powers of that mesoblast. It is not difficult to imagine, moreover, that partially developed and embryonic tissue will have a higher reproductive tension than fully developed tissue. In advanced age the reverse is usually more marked, since the mesoblast is notoriously atrophic—so also is the epiblast to a lesser degree perhaps, but the work meted out to the epiblast is not proportionately decreased, and, as Mr. Marsden points out, in the case of chronic simple ulcer it is enormously increased as far as the call upon its reproductive powers are concerned.

Thus the "tissue tension" of the epiblast exceeds that of the atrophic mesoblast, and hence the invasion called epithelioma. The same applies to the hypoblast in its relation to the mesoblast, since many elderly people eat far too much, and are frequently constipated and take little exercise. I have heard it stated that malignant disease is due to primary degeneration of the basement membranes; but I imagine the proof of this would be difficult to obtain even if it were shown what part the basement membranes played in keeping the cells in their proper place. Doubtless these theories are as "old as the hills," and I venture to predict that the causation of tumours will be discovered by the bacteriologist and not by the morbid histologist or embryologist.

From the bacteriological point of view it may be assumed that the parasite is one against which the leucocyte is of little avail, or is but slowly influenced by chemotaxis, and to which ordinary granulation tissue by itself is no barrier. Therefore the epithelial cells, to which the parasite strongly appeals, reproduce and endeavour to limit and wall off the invaders. This they are unable to perform successfully, but nevertheless greatly impede their progress; especially in rodent ulcer are they most successful.

In secondary deposits epithelial cells are carried off by the lymph stream to the liver or elsewhere, as also is the parasite, there to start the unequal fight once more, for maybe the epithelial cell is a comparative novice at warfare.

The shrinking of a scirrhus is analogous to the contraction of ordinary granulation tissue. Likewise it may be conceived that the parasite of sarcoma is resisted by the connective tissue cells of the mesoblast, which attain a great size when successful. After all, why should we look to the leucocytes to fight every kind of marauder unaided?—I am, etc.,

Reading, June 6th.

CECIL E. REYNOLDS.

OPERATIONS ON THE PROSTATE.

SIR,—Dr. Howat's somewhat trenchant criticisms of my procedure in the case of enlarged prostate, reported in the JOURNAL of May 22nd, demand a reply, not only to satisfy him but also all others who hold similar and, in my opinion, erroneous views as to the value of suprapubic cystotomy in cases of enlarged prostate.

After all, the mortality of suprapubic prostatectomy is not high when one considers the age of the patients and the condition of the bladder and kidneys often present. Mr. Freyer's results, showing a mortality of about 7 per cent. in a large series of cases of all sorts, speak for themselves, and at the meeting of the British Medical Association at which my case was described I reported a small series of 23 cases with one death. The ages of my patients varied from 53 to 79 years. One old man, aged 79, who was operated on for severe haemorrhage, had a double aortic murmur, and is still alive and comfortable one year after. Another weighed 20 st., and had a weak heart, but made an excellent recovery. Other surgeons have had similar results.

Dr. Howat asks whether, when the bladder was opened, examination gave any indication of the degree of difficulty likely to be encountered. In reply to this I may say that on opening the bladder a large firm, elastic, lobulated mass, somewhat cone-shaped, presented almost immediately under the suprapubic wound. The internal opening of the urethra was situated at the apex of the projecting mass, a long finger-length from the neck of the bladder. Surrounding the growth was a deep trench, into the depths of which my finger could not quite reach. Consequently I did not feel the stone, which was not discovered until the prostate had been removed. The only difficulty I apprehended was the mechanical one of being unable to reach the limits of the growth with my finger. I have already reported how I met that difficulty. Dr. Howat agrees that operation was rightly considered, but argues that the operation chosen was the wrong one. He would have performed suprapubic cystotomy, with the object of relieving retention and checking the bleeding. Just so, but the retention having been relieved and the bleeding arrested, what was he prepared to do next? Wait for the suprapubic wound to close? In what other way was he going "to restore its former degree of efficiency (the italics are mine) to the bladder?" He must know that closure of a suprapubic wound is only likely to take place when there is free vent for the urine by the natural passage. Even a very moderate degree of obstruction is sufficient to prevent closure of a suprapubic sinus or to cause it to reopen when apparently soundly healed. In cases of enlarged prostate with obstruction closure of the sinus is certain to fail. Consequently the patient is doomed to that most distressing condition—a permanent fistula. Further, drainage of the bladder by the suprapubic route is very imperfect, and is only undertaken in septic cases prior to the performance of prostatectomy for the purpose of facility in washing out. In the case in question it will be seen that it would have been futile to have expected closure of the wound. The patient, who is a well-read man of a high degree of intelligence, had the alternatives, with all the attendant risks of prostatectomy fully explained to him, and he unhesitatingly accepted the radical operation, which, he was informed, would, if he survived, place him in a comfortable position as regards his urinary organs for the rest of his life. My medical colleagues were of opinion that though there was considerable risk with the operation, the patient had a reasonable chance of recovery, and they were further of

opinion that delay would not tend to improve the condition of his heart and might be dangerous from the advent of sepsis in his bladder. If any operation were to be performed it would have to be done at once and completed once for all, as the probability was that further operative interference later on would prove too much for him. The patient had a fight for life, but has succeeded beyond my most sanguine expectations, and is now, five weeks after operation, able to be up every day. His wound is dry and he can already retain his urine for five hours, and pass it with ease and freedom.

I would recommend Dr. Howat to reconsider carefully the advisability of performing suprapubic cystotomy in similar cases, unless he is prepared to contemplate the certainty of the persistence of a suprapubic fistula, through which all or most of the patient's urine will be voided, a condition which can only be successfully dealt with by a subsequent prostatectomy.—I am, etc.,

Belfast, June 7th.

ANDREW FULLERTON.

SIR,—Dr. R. K. Howat's able and unbiased criticism from a clinical standpoint (p. 1392) on the acquisition of a record prostatic trophy by Mr. Andrew Fullerton is one that will have the endorsement of clinicians. Dr. Howat, perhaps intentionally, omits to question why, in the presence of gravel and haematuria, a radiograph was not taken in this case as a preliminary diagnostic measure.

My excuse, however, for troubling you is to confirm the views expressed on p. 1301 of the previous issue of the JOURNAL by Dr. Alfred Codd, of Wolverhampton, on the treatment of enlarged prostates directly by the x rays. If Dr. Howat's line of treatment had been followed, after removal of the calculus, this prostate could have been thus resolved, in so far as its neoplastic tissues were concerned, and the urinary function restored.

Your comments on the function of the prostate on p. 1382, drawing attention to Professor C. Posner's contribution on this subject, are interesting in this reference. May I be permitted to suggest that, as in circumcision, the rule has been for eunuchs to be castrated in infancy or early life, and it is natural for the development of the prostate to be thus arrested in the absence of the testicular hormones? A similar influence being known to follow ovariectomy in young mammals in their mammary development, a fact, indeed, which was also responsible for the application of ovariectomy in the last decade as a remedial measure for mammary cancer, but now of merely historic importance.

The failure of castration as practised in the last decade of the nineteenth century for reducing the enlarged prostate in the aged might be accounted for if it is realized that in the vast majority of such cases the enlargement is not intrinsic and parenchymal, but is interstitial and fibrotic, the sequela of long-standing chronic prostatitis. The senescence of the emunctories, atony of the intestines, with constipation and pre-existing urethral and cystic infection, are doubtless important etiological factors to be borne in mind. Castration in the aged could not, therefore, be expected to do more than remove certain sexual reflexes, thus preventing periodic congestion in the gland.

From the small but gratifying experience radiotherapy has afforded in quickly reducing both enlarged tonsils and enlarged prostates, by means of the filtered x rays, on the basis of the impact of the negatively charged molecules of matter, travelling at high velocity through the large protein molecules, which constitute the cytoplasm of all transitional cells, splitting them up and thus rendering the smaller molecules and debris more diffusible and capable of excretion without damage to the somatic cell elements, their more extended adoption in cases uncomplicated by calculus is to be recommended.—I am, etc.,

London, W., June 5th.

H. D. McCULLOCH.

SECONDARY PAROTITIS.

SIR,—I have read with interest in the BRITISH MEDICAL JOURNAL of May 29th the paper by Dr. H. D. Rolleston and Mr. M. W. B. Oliver, and also the note on the same subject by Dr. W. Soltan Fenwick. In simple terms the former show that abstinence from food is a leading factor in the production of secondary parotitis, while the latter recommends chewing as a prophylactic measure. The

practical value of these observations is considerable, but I should like to draw attention to what I believe to be an additional factor in the causation of secondary parotitis—namely, morphine.

Taking a wide view of the subject, there is little doubt that the affection is due to the coincidence of two conditions—infection and stasis. If it were possible to eliminate one of these factors, there would be no secondary parotitis. I have seen it stated that the affection can be prevented by oral disinfection. This may be correct; but, if so, the requisite degree of oral cleanliness is difficult of attainment, as the following case will show.

A few years ago a dentist's assistant was under my care for a perforated duodenal ulcer. After the operation I ordered him a carbolic acid mouth wash, and some antiseptic lozenges to suck. In spite of these prophylactic measures both parotids became inflamed and suppurated, causing a prolonged and complicated convalescence. The patient had been given morphine. A careful examination of his mouth did not reveal a spot of dental caries, and one could hardly expect to have again a case so favourable for oral sepsis. Since then at least six cases of secondary parotitis have come under my personal observation, and in every case morphine had been given.

A short while ago a patient of mine was suffering from cerebral thrombosis. Nourishment could be given only with difficulty, and was confined to fluids; thus there was no chewing. The patient was so restless and even violent that she was given hypodermic injections of morphine. Her breath was foul, and the united exertions of two nurses failed to cleanse her mouth. Here were the conditions for parotitis, namely, a septic mouth, absence of chewing, and the administration of morphine; and as a matter of fact a suppurative parotitis ensued. I think that most men would have failed, as I did, to anticipate the complication, partly because it has been associated in the literature chiefly with abdominal lesions. It is to be hoped that in the future this association will be regarded as in no way essential, for it is but a chance. The various causative factors are most commonly present in abdominal cases, but are not confined to these. Given any illness in which there is oral sepsis and arrest of the salivary flow, and parotitis is apt to occur. It is probable also that the administration of morphine, together with the absence of chewing, plays an active part in arresting the salivary flow.—I am, etc.,

Southsea, June 8th.

HAROLD BURROWS.

THE PROFESSION, THE ASSOCIATION, AND THE JOURNAL.

SIR,—May I suggest to Dr. Cuthbertson Walker that the records of attendance at Branch and Division meetings indicate that about 90 per cent. of members belong to the Association for the sake of the JOURNAL alone?

Owing to the size of the Branches, only a small percentage of the men in the district can attend the meetings; in urban districts these men are the better-paid members of the profession whose "hours of business" do not run to 8, 9, or even 10 o'clock at night, and who live in the fashionable quarter of the town, that is to say, near the place of meeting. In rural districts, the men who attend are again those who have leisure, and who live in the town of meeting.

Few country practitioners can afford half a day for either outside business or pleasure, but they belong to the Association for the sake of the JOURNAL, which keeps them au courant of the progress of their art and in touch with medical politics.

The non-members of the Association are those who have no time to attend meetings, and no time or inclination to read a medical paper. To paraphrase Dr. Crawshaw, they say, "What can membership of the Association do for me?"

A new era of prosperity may open with the reception of the Charter, when the Association will be able to offer other inducements to join it; but much more might be accomplished by largely increasing the number of meetings, and holding them in rotation at different places.—I am, etc.,

Bristol, June 5th.

HARRY GREY.

THE NEW IRISH UNIVERSITIES.

SIR,—In a fortnight the statutes of the new Irish universities will have passed into law, so that any modifications must be made by Parliament at once.

Convocation of the Royal University—largely composed of medical men—has not been consulted about these statutes, and therefore they need amendment. The Convocation recommended the establishment of a degree of B.Sc. in Public Health. This has been done in Dublin and not in Belfast, but instead of being open to graduates of all universities in the *Medical Register*, is confined, apparently, to those who have taken the M.B. in the University of Dublin.

It is also complained that effort is made to shear Convocation of any real power by confining the power to call meetings of it to the Chancellor or Senate in Dublin, whilst in Belfast members can call a meeting. Power to elect a clerk of Convocation has hitherto lain with that body; now it is transferred to the Senate.

Hitherto Convocation of the Royal University elected a certain proportion, usually of medical men, to the Senate. This power is now taken from them for five years.

There is also a strong objection to persons who have been nominated members of the Senate of the new universities being elected to paid professorships or other posts of emolument. If such are elected they should resign from the Senate forthwith. The institution of a degree of D.Sc. in Veterinary Medicine is desirable—there is a strong veterinary college in Dublin—but there is no provision for the study of diseases transmissible from animals to man. Such post-graduate study would be the result of the possibility of obtaining a higher qualification for a veterinary surgeon. In like manner a much-needed stimulus to the study of pharmacology would result from the granting of a B.Sc. degree in Pharmacology for registered pharmacists.—I am, etc.,

J. C. MCWALTER, M.A.R.U.I., M.D.Brux.,

Dublin, June 10th.

F.F.P.S.Glasg.

THEORY AND HYPOTHESIS.

SIR,—It would be pedantic to expect all persons, or any person at all times, to be logically exact in the use of the word "theory." But I think that my friend, Dr. Wm. Hunter, does himself insufficient credit in complaining that his opinion on a certain point is stated to be "only a theory" (BRITISH MEDICAL JOURNAL, June 12th, 1909, p. 1458). Surely a "theory" is a "scientific interpretation of fact," and if the point he makes on the subject of severe anaemias be really a theory, it must be true. If, however, the principle contended for be not a demonstrated truth, it should be called a "hypothesis," which may, or may not, now, or at some future time, be proved to be a "theory." Into the merits of the question between himself and Dr. Charles H. Melland (BRITISH MEDICAL JOURNAL, June 5th, 1909, p. 1349, col. ii, line 7) I cannot enter, but my regard for the personality and accomplishments of Dr. Hunter makes me venture to pull him up on this matter of expression in a letter in which he evidently aims to be exacting. It is not necessary for me to justify the definition of "theory" and "hypothesis" here quoted, as it is fully given by John Stuart Mill in his *System of Logic*, Book III, Chaps. xiii and xiv.

Colloquially, the word "theory" has often, if not generally, to do duty for hypothesis, but when language aims at scientific precision it is necessary to distinguish between the two.

I therefore trust that Dr. Wm. Hunter will accept my remarks as no intentional departure from either amiability or appreciation. (See also *Lancet*, April 26th, 1879, p. 289, line 16.)

Liverpool, June 13th, 1909.

RUSHTON PARKER.

THE LATE MR. C. G. WHEELHOUSE.

SIR,—It is proposed to place a brass in Filey Parish Church to commemorate the name of the above, whose services to humanity at large, and to Leeds and Filey in particular, deserve some public recognition.

The brass will be placed immediately below a stained-glass window which he erected, and opposite the place where for nineteen years he worshipped.

Mr. Wheelhouse had many friends, patients and pupils scattered about the country, and possibly some may wish

to share in this tribute to his memory. Subscriptions, limited to a sovereign, may be sent to the undersigned.

A. N. COOPER, Vicar.
HENRY FOSTER, Churchwardens.
A. V. MACHIN,

Filey, June 7th.

SURGICAL INSTRUMENTS: A WARNING.

SIR,—Will you permit me through your columns to warn medical practitioners to be careful in buying surgical instruments and apparatus from persons purporting to be agents of manufacturers or distributing firms selling such goods? In a case which has lately come before the Medical Defence Union a man representing himself to be an agent of a well-known firm of instrument makers sold to a surgeon a certain instrument and received payment for the same. Later the surgeon was written to by the firm in question, stating that the "agent" had in reality stolen the goods he was offering for sale, and making a demand either for the return of the instruments or payment of the value to them. The matter was placed in my hands, and on behalf of the surgeon I declined to carry out the suggestion made, as the action of the member concerned was bona fide and he had paid the price demanded by the agent, whose credentials he had to reason to disbelieve; and also stated that, should the firm desire to take the matter in court, our solicitors would be fully instructed to defend. Since the date of my letter I have heard nothing further. It would be as well for medical practitioners to merely give an order, and, when payment is required, to send a cheque to the business address of the firm, and not to pay the "agent" himself, unless absolutely certain that he is as he represents himself to be.—I am, etc.,

London, W.C., June 11th.

A. G. BATEMAN.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

Lectureships.

THE following reappointments have been made:

University Lecturer in Organic Chemistry.—Dr. Ruhemann.
University Lecturers in Chemistry.—Dr. Sell and Dr. Fenton.
University Lecturer in Physical Anthropology.—Dr. Duckworth.

University Lecturer in Special Pathology.—Mr. Strangeways.

Degrees.

The following degrees were conferred on June 10th:

M.D.—A. W. Izard, Trin.; C. N. Le Brocq, Pemb.; A. E. Martin, Down.
M.B., B.C.—E. Beaton, Govv. and Cai.; A. E. Burgess, Govv. and Cai.
M.B.—A. F. Jackson, Pemb.
B.C.—L. W. Sharp, Govv. and Cai.

The report of the syndicate on alterations for the general examination has passed the senate, one alternative being a preliminary examination in science in the subjects of the First M.B.—namely, chemistry, physics, and biology. A student who has passed this preliminary examination in science in all these subjects will be regarded as having passed the First M.B. Examination without the payment of an additional fee. The subjects may be passed separately.

UNIVERSITY OF LONDON.

SCHOOL OF MEDICINE FOR WOMEN.

THE Fishmongers Company has awarded a University Exhibition of £60 per annum for three years to Miss Naomi Tribe, a student of the school.

The Council has appointed Miss Kate Brown, M.B., B.S., to be Demonstrator in Anatomy and Curator of the Museum.

Lady Northcote will present the prizes and certificates to students for 1908-9 on Friday, July 2nd, when Mrs. Garrett Anderson will take the chair at 4 p.m.

UNIVERSITY OF BIRMINGHAM.

Endowment Fund.

THE first list of donations promised in response to the special appeal for the University Endowment Fund contains 125 names, and the total amount of the subscriptions is £75,859. The Chancellor (the Right Hon. J. Chamberlain, M.P.) heads the list with £100, £10,000 is subscribed by the Lord Mayor (Alderman G. H. Kenrick), and £2,000 by the Vice-Chancellor (Alderman Beale). Other large contributions are £30,000 from Sir Charles Holcroft, Bart., and £2,000 from Mr. J. A. Kenrick. Among donors of £1,000 each are the treasurer (Alderman Clayton), Sir John Holder, Bart., Messrs. W. A. Albright, J. S. Beale, W. Waters Butler, Barrow Cadbury, Neville Chamberlain, Edward Cheshire, Cregoe Colmore, F. Dudley Dockes, W. Gibbins, A. B. and C. B. Holmsworth, A. Keen, the

Right Hon. W. Kenrick, T. Grosvenor Lee, F. W. V. Mitchell, and H. F. Osler.

The Resignation of Mr. Bennett May.

Mr. Bennett May, F.R.C.S., has resigned his post as Professor of Surgery in the university, and the following resolution has been passed by the council:

That the resignation of Professor Bennett May be accepted with regret, and that the best thanks of the council be given to him for his valuable and distinguished services to the Birmingham Medical School during a period of thirty-three years.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

ORDINARY COUNCIL, JUNE 10TH, 1909.

Mr. HENRY MORRIS, President, in the Chair.

Fellowship Examinations.

At the recent examination in Anatomy and Physiology for the Fellowship 45 candidates were approved.

Diplomas of Fellowship were issued to 34 candidates found qualified at the final examination as follows:

Name.	Medical Qualification and School.
Charles Henry James, Maj. I.M.S....	... L.R.C.P. Lond., St. Thomas's.
Carlton Oldfield, Leeds M.D. Lond., Leeds.
Percy Montague Smith, London M.D. Lond., St. Mary's.
Edmund Arthur Dorrell, London L.R.C.P. Lond., Bristol and St. Bart's.
Archibald Hugh Pavan Dawnay, London L.R.C.P. Lond., St. Thomas's.
Walter Rodney Batty, Capt. I.M.S. Witleton	... M.B. Lond., St. Thomas's and St. Bart's.
Thomas Wilfrid Litchworth, Walton-on-Thames	... M.D. Lond., Camb. and St. Bart's.
William Herbert Forshaw, Newark	... L.R.C.P. Lond., London.
Aaron Levy, London M.D. McGill, St. Bart's.
John Jekyll Rainforth, Lincoln M.B. Lond., London.
Herbert Francis Woolfenden, Southport M.D. Lond., Liverpool and London.
Clifford Sidney White, London M.D. Lond., University College.
Robert Alfred Worthington, Hale Ead, near Chingford	... M.B. Lond., Camb. and Lond.
Frank Anderson Juler, London M.B. Camb., St. Mary's.
Thomas Charles Clare, Edgbaston	... M.B. Lond., Birmingham.
John Davis Barris, London L.R.C.P. Lond., Camb. and St. Bart's.
Thomas Braulley Layton, London	... M.D. Lond., Guy's.
James Eustace Rudolph McDonagh, London	... L.R.C.P. Lond., St. Bart's.
Sydney Gray MacDonald, Sydney M.B. Camb., St. Thomas's.
Hamilton Ernest Quick, Swansea	... M.B. Lond., St. Bart's.
Rupert Farrant, London L.R.C.P. Lond., Westminster.
Alexander Fleming, London M.B. Lond., St. Mary's.
James Leonard Joyce, Tenbury	... L.R.C.P. Lond., St. Bart's.
Christian Frederic Louis Leopoldt, Clarendon, Cape Colony	... L.R.C.P. Lond., Guy's.
William Fulton Neil, Dunedin, N.Z.	... M.B. New Zealand, New Zealand and Lond.
Cecil Frederick Robertson, London	... M.B. Lond., Middlesex.
Edward Kenneth Martin, Weston-super-Mare	... M.B. Lond., University College.
Robert Ollerenshaw, Glossop M.D. Viet., Manch. and Lond.
Hugh Raymond Guy Poate, Sydney M.B. Syd., Sydney and Lond.
Frederick Charles Pybus, Stockton-on-Tees M.B. Dur., Durham and St. Bart's.
Vincent Zachary Cope, London M.D. Lond., St. Mary's.
Arthur Cecil Devereux, Charlton M.B. Edin., Edin. and Middlesex.
William Maxwell Munby, North Shields M.B. Edin., Edin. and Lond.
Laurence Christopher Panting, Truro M.B. Oxon., Oxford, and Guy's.

Report of the Committee on By-Laws.

As requested by the Council on May 15th, 1909, the Committee has taken into consideration the copy of a letter addressed by the Society of Members to the Home Secretary and sent by him to Mr. Wilde for the observations of the College in reply. The Society asked the Home Secretary not to sanction the by-law relating to the admission of women to the College diplomas on the grounds:

1. That it is not necessary.
2. That it places women in an inferior position under an Act not adopted by any other qualifying body.
3. That paragraph 1 is in flat contradiction to paragraph 2.
4. That women will be invidiously treated under the scheme for a future London degree.
5. That the Council has throughout this matter acted directly in the face of the opinion expressed by the Fellows and Members of the College.

The following reply was forwarded by the Committee on the authority given it by the Council to the Secretary of State.

1. It is not customary and it is unnecessary for the College to apply for a Charter to effect changes which it has the power to effect by by-law. The power to admit women to examination for the diplomas of the College is given by the Medical Act, 1876, and the by-law has been made in accordance with the provisions of that Act.

2. The Medical Act of 1876 clearly contemplates a difference in the corporate standing of men and women admitted to medical qualifications, and the Royal College of Surgeons is entitled to give effect to this definite provision of the Legislature.

The property of the College is not vested in the existing Members, but in the body corporate. Members upon their admission pay a fee, in return for which they receive a diploma entitling them, in association with the licence of the Royal College of Physicians, to registration, and to other professional and collegiate privileges, but they pay no further fee or subscription.

If on petition being made at any future time by the College, the Crown should be advised to grant a Charter giving full corporate rights to women, the fact that the by-law now proposed existed would not place women in any worse position than that in which they are at present.

3. The Royal College of Surgeons is not comparable to a university with its numerous faculties, and there is no reason why it should follow the example of such bodies in framing its regulations. It may be pointed out that the course adopted by the Royal College of Surgeons is the same as that adopted by the Royal College of Physicians of London.

4. In the scheme for conjoint examinations by the Royal Colleges of Physicians and Surgeons and the University of London, it is contemplated that three qualifications should be granted, each of which would be held subject to the laws and regulations in force at the particular institution from which it was derived.

There is nothing anomalous or unprecedented in this arrangement, and indeed it is the position which actually prevails at the present time with regard to those who hold more than one degree or diploma.

5. The quotation in paragraph 5 of the letter from the "Society of Members," with regard to Clause 1 of the proposed By-law XXVI, by omitting the important words, "subject to the provisions therein and hereinafter contained," endeavours to show that the By-law is contradictory in its terms, but these words prevent this being the case.

6. The result of the Poll taken by the Council is set forth in the accompanying document. It will be seen that more than one-third of the Members to whom circulars were sent failed to express any opinion. As regards the supplementary poll mentioned, the Council has no information regarding the number and nature of the replies received, nor, so far as it is aware, have these particulars been published.

The foregoing was adopted by the Council.

Report of the Committee on Anaesthetics.

The Committee recommended that the following be added to the regulations for the licence in Dental Surgery:

6. Of having attended at a recognized dental hospital and school

(b) A course of practical instruction in the administration of such anaesthetics as are in common use in Dental Surgery.

The Committee further recommended that a certificate of such attendance be required of all candidates for the licence in Dental Surgery of the College who enter at a recognized dental hospital or school on or after October 1st next.

This was adopted by the Council.

Examiner in Dental Surgery.

Mr. Haslam was appointed a member of the Board of Examiners in Dental Surgery in the vacancy occasioned by the retirement of Mr. A. Pearce Gould.

Examiners for the Membership and Fellowship, and the Diploma in Public Health for the Ensuing Year.

The following appointments were made:

Elementary Biology.—James P. Hill, Thomas William Shore
Anatomy.—Wm. Hy. Clayton Greene, Arthur Robinson, William Wright.

Physiology.—Ernest Henry Starling, Benjamin Moore.

For the Fellowship:

Anatomy.—Charles Herbert Fagge, Frederick Gwynne Parsons, James Sherren, Arthur Thomson.

Physiology.—George Alfred Buckmaster, E. W. Vace Carlier, Charles Frederick Myers-Ward, William Henry Thompson.

Medicine.—Hugh James Moore Playfair, William Rivers Pollock, James Henry Targatz, Walter William Hunt.

Diploma in Public Health.—Part I, Harold Robert Dacre Spitta.

Part II, Richard Deane Sweeting.

University of Bristol.

Mr. R. J. Godlee was appointed the Representative of the College on the Court of the University of Bristol.

Arts and Gale Lectures.

The Arts and Gale Lectures, which were to have been given in June by Dr. G. Elliot Smith, have been unavoidably postponed until the winter.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

An extraordinary comitia was held at the college on Wednesday, June 16th, the President, Sir R. Douglas Powell, in the chair.

Lectures.

The following appointments were announced for the year 1910: Gulstonian Lecturer, Dr. Joseph Shaw Bolton; Lumenian Lecturer, Professor Osler; Oliver-Sharpey Lecturer, Dr. Mott; FitzPatrick Lecturer, Professor Sir Clifford Allbutt; Horace Dobell Lecturer, Dr. Wm. Bullock; Croonian Lecturer, Dr. F. W. Andrews, vice Dr. Arthur Gamgee, deceased. Dr. Henry Head was appointed Croonian Lecturer for the year 1911.

Darwin Anniversary.

The College Seal was affixed to an address to the University of Cambridge on the Darwin Anniversary.

Communications.

The following communications were received:

1. From the Secretary of the College of Surgeons, reporting proceedings of their Council on June 10th.

2. From the Rev. John G. Geare, of Farnham Rectory, Bishop's Stortford, asking leave to have a photograph taken of the portrait of Dr. Richard Hale (1670-1728) in possession of the College. Permission was granted subject to the usual restrictions.

University of Bristol.

On the nomination of the President, Sir William Church was appointed the Representative of the College on the Court of Governors of the new University of Bristol.

Report.

A report was received from the Representative of the College on the General Medical Council, Dr. Norman Moore, on the proceedings of the Council at their May session.

THE CONJOINT BOARD IN ENGLAND.

Syllabus of Examination for D.P.H.

The secretary of the Conjoint Board of the Royal Colleges of Physicians and Surgeons in England gives notice that on and after January 1st, 1910, a new syllabus for Parts I and II of the examination for the Diploma in Public Health will be adopted. Copies can be obtained on application to the secretary at the Examination Hall, Victoria Embankment.

The Services.

TERRITORIAL FORCE.

AMBUCLANCE COMPETITION IN LONDON.

The competition for the Hamilton Challenge Bowl took place on Monday at the head quarters of the 5th London Rifles, Finsbury Row, City, and was won by a squad of six men, under Lance-Corporal A. Gray, drawn from the 1st City of London Field Ambulance, R.A.M.C.T.F. The subjects included first-aid and stretcher drill, and the competition was open to all the medical units of the 1st and 2nd London Divisions Territorial Force, and to all regimental stretcher bearers and cadet corps. The examiners were Surgeon-Colonel W. Colver James, M.D., F.R.C.S., Honourable Artillery Company, and Major A. Ducat, M.B., Royal Artillery Corps T.F.

The Challenge Bowl was presented by the late Surgeon-General J. B. Hamilton, M.D., A.M.S., and has been keenly competed for by N.C.O.'s and men of the Volunteer Force for many years. Colonel P. B. Giles, F.R.C.S., A.M.O., 1st London Division, in announcing the result, stated that the Challenge Bowl would be held for twelve months by the Officer Commanding 1st City of London Field Ambulance, and that the conditions of the competition would be changed from time to time.

Medico-Legal.

PRACTICE BY UNQUALIFIED DENTISTS.

A DECISION of considerable importance to those whose duty it is to suppress the practice of dentistry by unqualified persons has been recently pronounced by the Court of Appeal. The facts of the case as stated were that certain persons entered into partnership to carry on the business of "the extraction and adaptation of teeth." It was a term of the articles that if any member of the firm should take any title, or do anything which should contravene the Dentists Act, 1878, the other partners should be at liberty to terminate the partnership.

Section 3 of that Act provides that a person shall not be entitled to take the name or title of "dentist" (either alone or in combination with any other word or words), or of "dental practitioner," or any name, title, addition, or description implying that he is registered or that he is a person specially qualified to practise dentistry unless he is registered. Two members of the firm fixed upon the partnership premises the following notice: "Bellerby, Heyworth, and Bowen. Finest artificial teeth. Painless

extraction. Advice free. Mr. Heyworth attends here." This was alleged to be a breach of the partnership articles, and good ground for dissolution. Acting on the decision of the King's Bench Division in the case of *Barnes v. Brown*, which was pronounced on October 14th, 1908, Mr. Justice Parker dissolved the partnership. The defendants appealed on the ground that *Barnes v. Brown* was wrongly decided:

That was a case in which the appellant carried on a dentist's practice at premises on the inner door and window of which he exhibited his name and a notice as follows: "H. J. Barnes. Finest Artificial Teeth at Moderate Prices. Extractions. Advice Free. Hours 10-7. English and American Teeth. Advice Free. Painless Extractions." He was convicted of having taken and used a description implying that he was specially qualified to practise dentistry. It was held that there was evidence upon which he could be convicted of an offence under Section 3 of the Act.

After a protracted argument, the Court of Appeal dissented from the view taken by the King's Bench Judges in *Barnes v. Brown*, and reversed the decision of Mr. Justice Parker. In effect this is a pronouncement by the Court of Appeal that the use of such a notice is lawful. The Master of the Rolls said: "As I read the section, it is directed to the personal description of the man as distinguished from the work he does. I cannot find any personal description which brings the present case within the Act."

It is to be observed that the meaning of the words "specially qualified" was not considered by the Court of Appeal, inasmuch as it was not necessary for the purposes of the decision; and it is important to notice that the Lord Chief Justice, in giving judgement in *Barnes v. Brown*, said it was a question of fact for the magistrate to decide whether the defendant had held himself out as specially qualified. Mr. Plowden was of opinion that where a man announces "painless extractions" he professes the highest degree of skill.

Having regard to the object of this legislation, namely, the protection of the public, the decision of this question of fact should always be left to the magistrate. He hears the evidence, and he is surely the best person to decide whether the public are likely to be induced to believe that the irregular practitioner is specially qualified. A case recently at a Dublin police court may be cited in this connexion. The Irish Branch of the British Dental Association took out two summonses against Mr. J. Byrne for unlawfully using the following descriptions:

Consult Mr. Byrne, The worlds expert adapter of teeth; he renders you original advice on the treatment, acquired through his vast experience of 25 years abroad; decayed teeth infallibly treated by Natures' own remedy; shattered health restored; all parties delighted; consultations free; hours 9 till 6. Metropolitan address. 36 Talbot St. N.B.—Letter appointments specially attended to.

The defendant had also issued this notice:

Are you wanting artificial teeth, or a misfitting case remade? Then come in and I guarantee my work for life. Installments taken. Fillings with gold or any of the fifteen amalgams, all one fee, 2s. 6d. Extractions (by my secret method without gas, cocaine, or other drugs) one fee only 1s. Mr. Byrne, 36 Talbot St.

A witness said that he called at the defendant's premises and made an appointment with him. The defendant examined his mouth, and mentioned the fee that would be charged. Upon the authorities cited to him the magistrate convicted the defendant, and fined him £5 for each offence, and gave £3s. costs. The report of the proceedings which appeared in the *Irish Times* did not mention the case of *Barnes v. Brown*, but it was probably relied on to support the conviction. If the effect of the decision of the Court of Appeal is to legalize advertisements of this kind, it would seem that the whole object of S. 3 of the Dentists Act has been largely frustrated.

In spite of the reverse which the British Dental Association has suffered by the case of *Barnes v. Brown* being overruled—if it has been overruled—it is to be congratulated upon the suppression of one form of unqualified practice—namely, practice by a limited company. In *Jaffe's* case, which was heard by an Irish Court in 1904, it was decided that a company not being a "person" could not be convicted of an offence under S. 3 of the Dentists Act. Relying on this decision a company named "Myddletons, Limited," attempted to practise dentistry, but in 1907 the Irish Court of Appeal granted an injunction restraining the company and its directors from adopting such titles as would lead persons to believe that qualified dentists were being employed. Commenting on *Jaffe's* case in *Attorney-General v. Myddletons, Limited*, Mr. Justice Barton said:

I am disposed to think that the defendant's counsel have endeavoured to found on *Jaffe's* case a larger claim of privilege for companies than the decision in that case will support. The claim for limited companies, as a result of that case, an unrestricted right to use the word "dentist" or its synonyms in any and every shape, and in any and every context. That case decided that the word "person" in Section 3 of the Dentists Act, 1878, does not include artificial person; and that

the section hits individuals, but does not hit limited companies. But a company, although it may be exempted from the penalties imposed by that section, is not, in my opinion, thereby privileged to make false representations, which are calculated to mislead the public as to the qualifications of the individuals whom it comprises or employs. I think that the official documents and advertisements to which I have referred contain representations of that kind. There may be other advertisements or announcements of the same kind. Each might have to be considered on its own merits.

Company practice has also been restrained in England. Thus, in a case decided by a judge of the English Chancery Division in January of this year, an action was brought, at the instance of the British Dental Association, against a company named "George C. Smith (Ltd.)," and against George C. Smith, the sole director, for alleged breaches of the Dentists Act. It appeared that the company had been formed to carry on the business of Smith, who had been on the *Register*, but was struck off in May, 1906. Since that date several convictions had been secured against him. The company was alleged to be unlawfully carrying on the practice or business of dentists at several places in the metropolis and elsewhere. As a result of the case, which was not defended, an injunction was granted perpetually restraining the company "from representing" that they are carrying on, or intend to carry on, the profession or business of a dentist or surgeon dentist as successors to George C. Smith, surgeon dentist, or that they are dentists or dental practitioners, or by any name, title, addition, or description, or any title, addition to a name, designation, or description, whether expressed in words or letters, or partly in one way or partly in another, implying that they are registered under the Dentists Act, 1878, or are persons specially qualified to practise dentistry.

As was pointed out by Sir Donald MacAlister in his presidential address to the General Medical Council, these decisions not only prevent practice by companies, but they practically impose upon companies the same disabilities as are now imposed on individual persons.

DOAN'S PILLS.

AT an inquest in Lowestoft on June 3rd evidence was given to the effect that the deceased, a man aged 39, had refused to seek medical advice during a long illness because he was relying on a secret nostrum. A medical man usually called in found him in a dying condition with marked dropsy and gangrene of the feet and scrotum. Death, he said, was due to renal disease aggravated by the excessive use of the pills and the want of proper medical treatment. The jury returned a verdict in accordance with this testimony. The pills in question were, we are informed, Doan's backache and kidney pills, though this is not mentioned in the report of the case in the local newspaper. In an article published in the *British Medical Journal* for December 8th, 1906, the probable composition of twenty such pills was shown to be: Juniper oil, 1 drop; henlock pitch, 10 grains; potassium nitrate, 5 grains; powdered fenugreek, 17 grains; wheat flour, 4 grains; maize starch, 2 grains.

A PROSECUTION UNDER THE MIDWIVES ACT.

A CASE of considerable interest to medical men was heard recently at the Eccles Borough Police Court on Monday, May 10th. Under the Midwives Act of 1902, Sarah Ann Marsh was summoned for procuring admission to the Midwives' Roll for Lancashire by a false and fraudulent certificate, and Dr. G. Sidley, Vice-Chairman of the Eccles Health Committee and a member of the Education Committee, was summoned for aiding and abetting. Mr. Lewis, of the Office of the Director of Public Prosecutions, conducted the prosecution, and Mr. F. Ogden, instructed by the Medical Defence Union, defended Dr. Sidley. It was stated in evidence that Mrs. Marsh, having been in bona-fide practice as a midwife since 1899, applied within two years of the passing of the Midwives Act to be placed on the roll of Lancashire midwives. For that purpose she called on Dr. Sidley, who at her request signed a certificate to the effect that she was "sober, trustworthy, and of good moral character." The certificate was sent to the Central Midwives Board, and Mr. G. W. Duncan, Secretary of the board, who gave evidence, said that in consequence of the certificate she was admitted to the roll of midwives on April, 1905. She practised as a midwife until February, 1909, when she was convicted at Eccles of being drunk and incapable, and was fined 5s. and costs. This was reported to the Central Midwives Board, and inquiries were then made as to her previous history. It was then found that previous to her obtaining the certificate from Dr. Sidley, on the strength of which she was admitted to the roll, she had been convicted eight times of being drunk and disorderly, and after that date she was again convicted four times on similar occasions sent to prison for a week and a month respectively. In March last her name was erased from the Midwives' Roll, and Mr. Duncan brought the case to the notice of the Director of Public Prosecutions, who thereupon instituted the present actions against Mrs. Marsh and Dr. Sidley.

For Dr. Sidley it was pleaded that he had first known Mrs. Marsh as a night nurse at the Eccles and Patricroft Hospital at which he was honorary surgeon; he had also frequently met her at Patricroft in her capacity as nurse, and had always found

her trustworthy. He had not the least idea when he signed the certificate that she had ever been convicted of drunkenness, and what he did could not be said to be false or fraudulent. Neither had he acted recklessly, as in signing the certificate he spoke not from mere hearsay but entirely depended on his own personal knowledge of Mrs. Marsh. To give a false certificate wilfully would be a misdemeanour under the Act, and no one would believe for one moment that Dr. Sidley had been guilty of issuing a false certificate merely to enable a woman to earn her living as a midwife. After a short absence from court, the magistrates were unanimously of opinion that there was not even a *prima facie* case against Dr. Sidley, and the case against him was dismissed. Mrs. Marsh, however, was committed for trial at the Quarter Sessions.

The case came up again at the Salford Sessions on Monday, May 24th, when Mrs. Marsh was brought up on the charge above stated. Mr. Gordon Hewart appeared on behalf of the Public Prosecutor. Similar evidence was given to that previously given before the Eccles Magistrates. Mr. G. W. Duncan, Secretary of the Central Midwives Board, said that the prisoner having been convicted several times of drunkenness, was unfit to hold a certificate as a midwife. There was, however, no evidence that she had ever neglected a case or attended one while under the influence of drink. Dr. Sidley gave evidence to the effect that when he signed the certificate he did not know that she had been convicted of drunkenness, or he would certainly not have signed any certificate. For the defence it was pleaded that the words "sober, trustworthy, and of good moral character" were only intended to apply in her capacity as a midwife, and the fact that she occasionally got drunk when not attending a case did not affect the question, as there was no suggestion that she had ever endangered the life of any woman or child whom she had charge of. The jury found that the prisoner was guilty, but that she had acted in ignorance, not realizing the full purport of the letter she took to the doctor, and so they recommended her to mercy. The Chairman said that, as she had already lost her livelihood by this offence, that was some punishment, and he bound her over in her own recognizances of £5 to come up for judgement when called upon; he trusted the case would act as a warning to others.

CONDITIONS OF SALE OF PRACTICE.

Ctesiphore writes that A. sold a dispensing practice with the usual restrictions, but an asset in the practice was the sale of what is called a "specialty." The said specialty consisting of a particular form of tonic. One of his old patients who had been taking this preparation went to A. at his new home and procured a supply of it, but A. told the patient that in future his successor would supply it to him. "Ctesiphore" wishes to know whether this was legal?

*A. should refuse to see any of his old patients, but so far as the legality of his action is concerned all would depend upon the terms of the contract of sale. We notice that the complainant is not the person who purchased the practice from A., but his successor, and it is doubtful whether any agreement between A. and B. would be held to be equally binding between A. and C. We should not have thought that the sale of what purports to be a secret remedy would have formed a part of the practice of a registered medical practitioner.

MEDICAL WITNESSES' FEES.

T. R. A. has been subpoenaed to give evidence at a county court on behalf of an insurance company in an arbitration under the Workmen's Compensation Act. He wishes to know what fee he is entitled to charge the company, and whether he can demand his fee before entering the witness box.

*A. Before being sworn, he is entitled to ask that his legal fees shall be guaranteed by the party issuing the subpoena, but these fees are only from ten to twenty shillings a day, and mileage of sixpence a mile one way.

CERTIFICATES FOR INSURANCE COMPANIES.

H. H. S. writes that he has on several occasions been asked for duplicate death certificates for insurance offices in which the deceased held policies, but the offices have declined to take any death certificate save that issued by the registrar. He wishes to know if this is the law.

*A. The insurance offices are fulfilling a statutory obligation. It is illegal for them to pay any policy without the production of a copy of the registration of the death, which can only be furnished by the registrar. Some insurance companies require a special certificate from the medical attendant on the deceased, in addition to the registrar's certificate. A medical practitioner is perfectly justified in charging a fee for this.

THE PHARMACY ACTS.

BARNBY.—Medical practitioners, by Section 1 of the Pharmacy Act Amendment Act, 1899, are exempted from all the restrictions in the first fifteen sections of the Pharmacy Act, 1868. We may refer our correspondent to a decision on the use of the word "pharmacy" as the description of a place where business is carried on by a person who is not registered under

the Pharmacy Act, 1852, given by Judge Shand in the St. Helens County Court on March 31st. In giving judgement for the Pharmaceutical Society, Judge Shand said, "The use of the word is a sign implying that the person carrying on business in that place is one registered under the Act, or a person duly qualified to dispense medicines, as required by the Act." Leave was granted to the defendant to appeal against this finding. So there the matter rests at present until the appeal is disposed of.

Medico-Ethical.

The advice given in this column for the assistance of members is based on medico-ethical principles generally recognized by the profession, but must not be taken as representing direct findings of the Central Ethical Committee.

GRATIS ATTENDANCE ON MEDICAL PRACTITIONERS. ANTIGRABER can, of course, if he chooses, write to the practitioner and tender the amount which he thinks fair.

A DOCTOR'S CERTIFICATE.

W. A. S. R.—In reply to our correspondent, we would say that a fee of £1 is. would not have been too much, having regard to the fact that a visit was required and the important nature of the certificate. Our correspondent was expected to make a most careful examination, and to take detailed notes of the case, having in view the possibility of his being called upon to give testimony in a court on oath.

SUPERSESSION.

E. F. L. DE J.—(1) The patient was justified in going to Dr. B. (2) Dr. B. was justified in attending. (3) Dr. B. should have offered to retire in favour of Dr. A., but if the patient insists and refuses to allow Dr. A. to attend, Dr. B. may continue to treat the case to the end, but he should avoid taking over the patient if possible. Dr. A.'s arrangements for night calls seem to be faulty.

THE ACCIDENTS OF PRACTICE.

A DENTIST writes to say that in the course of extraction part of a root was broken off. It was deemed advisable to do nothing more at the time, but the patient was advised to come back if it gave any trouble. Six weeks later he heard that the patient was under the care of a medical practitioner. He called to see her, when it was found that there was an acute alveolar abscess, which was subsequently opened. Something seems to have been said about the possible risk of necrosis, and even of blood poisoning; and our correspondent complains that exaggerated reports are being circulated by the woman to the prejudice of the dentist, who is blamed. He asks what he is to do.

*A. We should strongly advise him to do nothing. This is the sort of accident that must happen from time to time in surgical or dental practice. If any really slanderous statements are made the dentist has a legal remedy, but he will probably best consult his own interests by allowing the matter to blow over, as no doubt it will very soon.

Public Health

AND

POOR LAW MEDICAL SERVICES.

THE EDINBURGH SMALL-POX HOSPITAL.

A SUBCOMMITTEE of the Public Health Committee of Edinburgh Town Council met on June 14th, with members of the Local Government Board, with reference to a suggestion by the latter body that the wooden erection used as a small-pox hospital within the grounds of Colinton Mains Hospital should be removed further from the main blocks of buildings. The officials of the Board urged that the hospital should be situated at as great a distance as possible from dwelling houses and buildings occupied by other patients; but the representatives of the city were not inclined to incur any fresh expenditure at the present time. After an exchange of views the matter was left as it stands at present.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

CITY OF COVENTRY.—The report for the year 1908 of the City of Coventry, by Dr. E. H. Snell, the Medical Officer of Health, contains the following principal features. Estimate population at the middle of the year, 91,000; birth-rate, 28.9; average for previous 10 years, 29.1; marriage rate, 17.0; average for previous 10 years, 17.2; death-rate, 13.3; average for previous 10 years, 15.5; infantile death-rate, 93 per 1,000 births; average for previous 10 years, 135; zymotic death-rate, 0.94; average for previous 10 years, 1.9; respiratory death-rate, excluding phthisis, 2.12; phthisis death-rate, 1.31; death-rate from other forms of tuberculosis, 0.45. There were 238 cases of scarlet fever with

7 deaths, 7 of typhoid fever with 1 death, 108 of diphtheria with 8 deaths, and 2 cases of puerperal fever with 1 death. Twenty deaths were registered as due to whooping-cough, and there were 235 alleged cases notified from the schools. With regard to vaccination, there were 2,536 births, 192 died unvaccinated, 1,524 were vaccinated, 1,346 were unvaccinated, and there were 964 declarations made of conscientious objections, so that of the children who survived only 63.4 per cent. were vaccinated. Eighty-three deaths were attributed to cancer and other forms of malignant disease. The result of the examination of 1,992 school children is shown in the following table:

Defects and Diseases.	Total Number.	Per Cent.
Head verminous	531	26.6
Ringworm	5	0.25
Teeth slightly decayed	330	16.0
Teeth much decayed	896	44.9
Tonsils slightly enlarged	169	8.4
Tonsils much enlarged	85	4.2
Enlarged glands in neck	779	39.1
External eye disease	52	2.6
Squint	17	0.8
Defective eyesight	45	2.2
Defective hearing	80	4.0
Heart disease	5	0.25
Lung disease (non-tuberculous)	29	1.4
Tuberculosis	6	0.3
Rickets	5	0.25
Deformities	39	1.9
Other defects	12	0.6
Defective speech	18	0.9
Defective nutrition	83	4.1
Debility	150	7.5
No defect found	303	15.2

An examination was made of the sight of 1,688 children who during the year were admitted to the senior departments, and of these no less than 362, or 21.3 per cent., were found to have either defective or very defective sight. The parents in all of these cases were communicated with and advised to seek advice. With regard to the verminous heads, the proportions were: Infants, boys 11.4 per cent., girls 40.4 per cent.; senior, boys 1.27 per cent., girls 47 per cent.

A MINISTER OF HEALTH.

DR. JOHN HIGHER (M.O.H., Workington) writes: I am glad to see from a report of the opening of the Whitechapel Exhibition that Mr. John Burns, towards the conclusion of his address, made a pronouncement of far-reaching importance. "As Minister of Public Health, I wish the exhibition good luck!"

To myself personally this declaration on the part of a responsible minister identifying himself with public health matters and creating himself for the time being Minister of Health, is particularly gratifying, for it is now something like twenty years ago when, in an address I delivered on "State Obligations in Matters of Public Health," I advocated the creation of a State Department of Public Health with a Minister at its head to deal with all matters affecting the sanitary well-being of the people of this country.

Since that time things have moved but slowly in the direction I indicated. Now, however, public opinion seems to be fast awakening to the truth of Lord Beaconsfield's policy of sewage, "Sanitas, sanitatum; sanitas," and a democratic minister does not disdain to style himself a "Minister of Health." So far this is distinctly encouraging. Will Mr. Burns take his courage in both hands? Will he dissociate the department of which he has constituted himself "Minister" from that of the Local Government Board, and create a State Department of Public Health, the duty of which shall be to devote itself exclusively to public health affairs?

I will not here go into details of what ought to be included in the work of this service, but briefly state as my opinion that, beginning with the Notification of Births Act, it ought to follow the subject from the cradle to the grave, including administration of Factory Acts, compensation, and old age pensions; and, having done all this, will be kindly consent to obliterate himself by, so far as the Public Health State Department Service is concerned, committing hari-kari, and allow someone of eminence and repute in sanitary affairs to direct and govern the said service, and to be in something more than name a "Minister of Health."

Obituary.

D. M. BOURNEVILLE, M.D.,
PHYSICIAN TO THE BICÊTRE, PARIS.

On the last Sunday in May there passed away, in his 69th year, a notable figure among our Parisian colleagues, Bourneville, for many years physician to the children's department of the Bicêtre. A man of the people, sprung from a yeoman stock in Normandy, he studied medicine in Paris, under the special guidance of Delasiauve, to whose *Journal of Mental Medicine* he contributed his earliest papers on idiots and epileptics. He took as the subject of his graduation thesis in 1870, "A Study of Clinical Thermometry in Cerebral Haemorrhage and other Brain Maladies."

He early showed a literary bent, and in association with such men as Pascal, Claude Bernard and Charcot, assisted in the publication of many valuable works, notably of the admirable lectures by the last named on diseases of the nervous system. After the Franco-German war, during which he acted as an ambulance surgeon, he founded the *Progrès Medical*, a weekly journal, which he continued to edit till a year or two ago. In 1879 he became Physician to the Bicêtre, a post he retained till 1905, when he reached the age of compulsory retirement. His clinics in this hospital, and perhaps more especially his annual reports under the title of *Recherches Cliniques et Thérapeutiques sur l'Épilepsie, l'Hystérie et l'Idiotie*, published during a long series of years, with the aid of his clinical assistants, and containing a mine of pathological treasure, gave him a wide reputation, and he was the leading Continental authority on all that concerned mentally abnormal children. He devoted much attention to reorganizing, at the Bicêtre, the arrangements for the education and training of the latter class, which had fallen into abeyance since the days of Séguin, providing, moreover, systematic instruction in useful industries. He also founded at Vitry, near Paris, a private establishment for defective children of the upper social class, and of this, as also of the Fondation Vallée, he remained Medical Director till his death. In addition to an original work on the *Care, Treatment, and Education of Idiotic and Backward Children*, he published, under the title of *The Library of Special Education*, valuable reprints of the works of Séguin and other helpful treatises. Thanks to his persevering efforts, a trial of day schools for special instruction of defective children has at length been made in Paris.

Bourneville's activities were, however, not limited to matters strictly professional, and in 1876 he was induced to take up municipal politics, chiefly with the view of remedying hospital abuses, and after serving seven years on the Municipal Council he was returned in 1883 as a representative of a division of Paris to the Chamber of Deputies. His efforts were mainly directed to the laicization of the hospital services and to the establishment of systematic professional instruction of "infirmiers and infirmières," both in hospitals and asylums. He also brought about a reorganization of the "Services Speciaux d'Accouchements." His reforming zeal occasionally involved him in differences with professional confrères and exposed him to the abuse and misrepresentation of the clerical party, but to the end he adhered fearlessly and unwaveringly to what he considered the path of duty.

His funeral, which took place on June 2nd, was attended by a large assembly of the nurses, attendants, and other members of the staffs of the hospitals and asylums of Paris, for whom he had done so much, and was honoured by the presence of representatives of the Government, the President of the Municipal Council, and the Director of Public Assistance.

THE LATE MR. G. H. HAMES.—In the obituary on Mr. Hames, which appeared in the *JOURNAL* of June 12th, it was stated that he was house-surgeon to Sir William Savory. We have been informed that it was to the late Mr. G. W. Callender that he was house-surgeon. The date was July to October, 1875. Mr. Hames was appointed house-physician to Dr. Southey for one year on April 1st, 1876.

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL. The offices of the British Medical Association and of the British Medical Journal are at 429, Strand, London.

Communications respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

ARSENIC IN HUMAN HAIR.

DR. STANLEY COLVER (Hullian) asks: What is the normal amount of arsenic found in human hair?

HOSPITAL WALLS AND FLOORS.

Savage (South Africa) asks for advice as to a durable and easily cleansed paint for walls of hospital wards; on what kind of plaster is such best applied; whether there are any other substitutes excepting glazed bricks and material of this kind; and what makes a good floor for an operating theatre.

STALE ASPARAGUS.

A. L. asks whether asparagus develops any deleterious properties if kept for a few days after being cut before it is cooked. Three gentlemen have suffered from vomiting and purging, commencing eight hours after the ingestion of asparagus, which had been cut three or four days before being boiled.

* We can find no record of asparagus producing the symptoms mentioned in any of a considerable number of authorities dealing with its use as food which have been consulted. Asparagus contains a high proportion of nitrogenous substances, of which more than half consist of various amides, and it would not be at all surprising if these underwent some change on keeping the cut vegetable whereby deleterious substances might be produced. The stem portion is said to contain ferments favourable to decomposition.

ANSWERS.

DESIGN FOR A SURGERY.

R., who has just finished building a surgery, writes, in reply to "T's" inquiry in the JOURNAL of June 5th, p. 1395: "My surgery is an annex to my dwelling house, and I only required three walls, the fourth being part of the gable of the house, through which a door was broken. My new surgery is 23 ft. long, 10 ft. wide, and 10 ft. high (outside measurements). The front is dressed stone to correspond with house, the sides and end of brick, 9 in. thick, and plastered with cement. The roof is wood, covered with thick felt and heavy corrugated iron. The estimate for that part of the work was £22 15s. Inside I have divided it into two rooms, one being 11 ft. by 9 ft. wide, and the other 9 ft. square. All inside is lined with dressed yellow pine, and has two coats of varnish. The smaller room I have fitted up as a dispensary, and it has a small counter, containing half a dozen drawers, and there is upwards of 60 ft. of shelves along the side wall. The front has a window and a door for patients, so that they need not come through my dwelling house. The cost of joiners' work, painting of doors, fitting up of electric bell, shelves, counter, etc., was £30, so that I had the whole building for a little less than £53.

LETTERS, NOTES, ETC.

LYNN THOMAS AND SKYRME FUND.

MR. WILLIAM SHEEN, M.B., F.R.C.S. (St. Andrew's Crescent, Cardiff) Honorary Secretary of this Fund, desires to acknowledge the following subscription:

D. C. Lloyd Owen, Birmingham... £1 1 0

SENILE GANGRENE.

DR. GEORGE MURRAY (Sunderland) writes: In June, 1908, I was called to see a man aged 70 suffering from gangrene in the great toe. It spread gradually up the limb until it reached the junction of the middle and upper third, where the line of demarcation formed. The soft parts sloughed in time until the bones were reached. About the middle of January, 1909, the patient sent for me, and, on examining the limb, to my surprise I found the gangrenous part of limb completely separated. The bones were eaten through. The hæmorrhage was very slight. The stump was nearly healed, except where the fibula and tibia protruded. Granulations slowly covered the ends of the bones, and now the stump has healed. The case is an interesting one, as it shows what can be done by leaving things to Nature. The limb was dressed antiseptically. Had he been operated upon, the shock would probably have killed him.

"HYPERTROPHIC OSTEO-ARTHRITIS OF HANDS WITHOUT VISCERAL OR CONSTITUTIONAL DISEASE."

DR. F. PARKES WEBER (London, W.) writes: May I point out that the title "Hypertrophic Osteo-arthritis" given to Mr. R. C. Worsley's interesting article in the BRITISH MEDICAL JOURNAL for June 12th (page 1411) is liable to give rise to some confusion in nomenclature? Mr. Worsley describes and illustrates a typical case of "giant growth" of portions of both hands, whereas the term "hypertrophic osteo-arthritis" is almost exclusively applied to the totally different condition known as pulmonary (or better, secondary) hypertrophic osteo-arthritis, described by Pierre Marie and others.

THE FINANCIAL PROSPECT OF MEDICINE.

DR. H. S. CHATE, M.B., B.Sc., D.P.H. (Twickenham), writes: The article under the above title is of great interest to the medical profession, especially to those who have recently qualified and are beginning to realize the prospects. But I would suggest that the ratio number of medical men to general population does not give a quite accurate idea of the amount of work for each medical man at the present time, as compared with the amount of work for each man twenty-eight years ago. For after all, it is not the number of possible patients, but rather the number of illnesses which determines the remuneration of the doctor. And there is no doubt that the amount of illness is much less than formerly, owing to improved sanitation and knowledge of hygiene. This applies more especially to infectious diseases, but also to some extent to general diseases. Dr. Newsholme, in his *Vital Statistics*, estimates, if I remember rightly, a decrease per annum of 50,000 cases of sickness since the passing of the Public Health Act, 1875.

Moreover, there are several factors at work at the present day to diminish sickness—for example, the inspection of school children, the Midwives Act, etc.

Hence it is practically certain that the increase of population has not brought with it corresponding increase of number of illnesses, and therefore the amount of work per medical man has decreased in much greater ratio than your figures represent.

* Our correspondent's point is the subject of the article, promise of which was made at page 1450 in the issue of the JOURNAL for June 12th.

ANAESTHETICS IN GENERAL PRACTICE.

DR. SYDNEY HAYNES (Birmingham) writes: While agreeing with Mr. Gardner, whose article on this subject appeared in the BRITISH MEDICAL JOURNAL of June 5th, p. 1353, on the advisability of keeping the air ways clear, I do not consider that it is always wise to retain even a weakly active corneal reflex, more especially in abdominal and other operations where any strain may prove injurious to the patient. Another point I may mention is that a too frequent testing of the corneae results in the loss of corneal sensibility, so that the anaesthetist who relies only on that test may fall into the error of considering the patient more deeply anaesthetized than he is. I agree with Mr. Gardner in his advocacy of the E_2C_2 mixture, which I believe to be safer as a routine anaesthetic than CHCl_3 , and am of opinion that all patients, whether children or not, should be lifted or moved as little as possible when anaesthetized.

SLEEP.

DR. H. G. H. NAYLOR (St. Kilda, Victoria) writes: As the subject of sleep has been under discussion in your columns lately, will you permit me to make a few remarks on this physiological condition? The idea of anaemia of the brain as a cause for the necessity for sleep is, in my opinion, not reasonable, otherwise cats and dogs must suffer with frequent attacks of brain anaemia daily. I think the inclination to sleep is to be accounted for by the retention of waste products from the absorption of unassimilated food, and from daily excitation, the stimulating the blood supply to the brain. One is often consulted by patients who want to sleep too long or not sufficiently long. Both conditions are relieved by a free clearing out of the mucinities, the bowels, and kidneys at the same time by a dose of about 2 grains or 3 grains of calomel, a drug which acts simultaneously on them both. I have often in my practice found a dose of calomel about three times a week enable the patient to sleep well and rid him of his inane woe and dreams, while at the same time he has been dieted.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	0 4 0
Each additional line	0 6
A whole column	2 13 4
A page	8 0 0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 429, Strand, London, not later than the first post on Wednesday morning preceding publication; and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

To be Stamped with a Penny Stamp and Posted.

BRITISH MEDICAL ASSOCIATION.

SEVENTY-SEVENTH ANNUAL MEETING.

JULY 27th, 28th, 29th, and 30th, 1909.

Members of the British Medical Association who intend to visit BELFAST during the Annual Meeting will greatly facilitate the labours of the Local Committee if they will fill up the following form and forward it by post as addressed on the other side. This will eventually be sent to the Head Office, London, to issue the necessary certificate to enable members to obtain Railway Tickets at reduced fares.

MEMBERS DESIRING ACCOMMODATION ARE REFERRED TO NEXT PAGES.

The Forms are intended for the use of Members of the British Medical Association exclusively.

It is my intention to be present at the ANNUAL MEETING in BELFAST,

*and I expect to be accompanied by**

Name

Address

* Here indicate whether accompanied by a lady, as separate vouchers are required to enable Members to obtain Railway Tickets at reduced fares.

It is my intention to be present at the ANNUAL DINNER of the Association on Wednesday Evening, July 28th, and I herewith enclose Cheque (or P.O.O.).†

Signature

† DINNER TICKET without Wine, but inclusive of Aerated Waters, 15s.
Wine to be paid for as ordered.

Cheques and Postal Orders should be made payable to the Secretary of the Executive Committee, CECIL SHAW, Esq., M.D., and enclosed in an envelope, together with this form, directed as on the reverse. Early application for Tickets is requested by the Committee, to enable them to provide accommodation and allot seats.

Remarks

ON A

CASE OF PNEUMOCOCCUS INVASION
OF THE THROATUPON WHICH LARYNGEAL AND PULMONARY
TUBERCULOSIS SUPERVENED.

BY

SIR FELIX SEMON, K.C.V.O., M.D., F.R.C.P.,

PHYSICIAN-EXTRAORDINARY TO HIS MAJESTY THE KING.

IN November, 1908, I delivered at the Polyclinic a lecture on the question of pneumococcus invasion of the throat, which was later on published in the *Medical Magazine* for December, 1908. In this lecture I described two cases of a hitherto unrecorded affection of the throat due to pneumococcus invasion. The material being so small, it was of course impossible to establish a full and characteristic picture of this new form, and I contented myself, after describing in detail the course of the affection in the two cases I had observed, with saying that I had "seen two cases of a throat affection which were characterized by a course entirely different from any known to me in other diseases of that part, namely, by showing the most surprising fluctuations between intensely painful inflammatory conditions of the throat and improvements which appeared to render complete and speedy recovery almost a certainty, but which repeatedly gave way to absolutely unexpected aggravations, until finally—in the one case certainly spontaneously, in the other one during an iodide of potassium treatment—complete recovery took place."

I further stated that these cases were characterized by profound asthenia, by ulceration of the affected parts, by an almost entirely afebrile course, and by complete absence of swelling of the cervical lymphatic glands; that in the first case pneumococci were present almost in pure culture, whilst in the second case the culture consisted predominatingly of pneumococci, and that in both cases towards the end a punched-out loss of substance occurred, whilst by far the greater part of the ulcers healed without leaving any scarring behind.

So far as I know, no further instances of pneumococcus invasion of the throat have been recorded since. Having lately had the opportunity of observing a third case, which ended fatally, owing to tuberculosis supervening upon the original infection, I consider it my duty to place its details on record.

Mr. H. R., aged 45, a well-known and universally respected member of our profession, suffered from sore throat early in September of last year whilst in Scotland. He consulted Dr. P. McBride of Edinburgh on September 25th, who found nothing but an enlargement of the lingual tonsil.

I saw the patient, who was a great friend of mine, on October 27th. He then complained of unpleasant sensations in the throat, which were referred to the region of the lingual tonsil. He had not felt well in Scotland, he told me, and shortly before his return the symptoms had localized themselves in the region of the base of his tongue. The lingual tonsil was found to be distinctly swollen, and was treated with applications of a solution of iodine and iodide of potassium (Lugol's solution). After a few applications the swelling decreased, and the patient for a few days felt better.

On November 5th he returned, complaining of distinct pain in the left side of his throat. An irregular superficial small ulcer, surrounded by a small area of whitish discoloration, was seen in the lateral wall of the throat, just opposite the last molar, and in its neighbourhood a few small irregular spots of white infiltration, but without loss of substance, were visible. The ulcer was not bigger than a split pea. It was cauterized with a weak chromic acid solution, and, as this proved of no avail, with a solution of nitrate of silver (60 grains to the oz.). For a time these applications afforded relief; usually, however, within a few days after disappearance of the ulcer, it reappeared, sometimes with, sometimes without, a whitish infiltration

in its neighbourhood. No enlargement of cervical glands was ever present.

The course of the affection induced me to think of a pneumococcus infection, as in several respects it corresponded to my first case, and on telling the patient of my suspicion, he submitted a specimen of a scraping from the ulcer to the bacteriological institute of his own hospital, with the result that an almost pure pneumococcus culture was obtained. After this I informed him that the affection would probably last a considerable time, but that ultimately recovery might be hoped for with certainty, to conclude from the issue in my previous two cases. For nearly two months the patient, who was devoted to his work, continued, in spite of his affection, to attend his private duties. On meeting him one day over a bad septic case, I strongly warned him not to expose himself to infection whilst his throat was in an ulcerated condition, but could not prevail upon him to take care of himself in this respect.

During the first days of the month of December he told me that he had been occasionally a little feverish. On December 15th the pharyngeal ulcer had again almost disappeared, but there was distinct swelling of the mucous membrane over both arytenoid cartilages without subjective symptoms of any kind. On December 21st there was again no recurrence of pharyngeal ulceration, but the mucous membrane over both arytenoid cartilages was very much swollen, partly oedematous, and the epiglottis too had very suddenly become tumefied and oedematous, so that the aspect of the larynx was almost typical of laryngeal tuberculosis. The patient's voice had become husky, and there was slight difficulty in swallowing. His pulse was quiet and the temperature was normal, but I sent him to bed all the same, asked him to put a Leiter's tube round his neck, to suck ice, and to live on cold fluid food only.

When I went to see him on the 22nd at his house, I found him considerably relieved, the swelling of the arytenoids had considerably diminished, that of the epiglottis was unchanged. I was very doubtful whether I should consent to his going into the country, as he had wished, on account of the laryngeal oedema, and ultimately arranged that he should come and see me next morning before going away. When he called on the 23rd, another considerable change had taken place; the oedema of the epiglottis was materially reduced in size from what it had been on the previous day, although it had not quite disappeared, whilst the oedema over the arytenoid cartilages, and indeed over the whole posterior wall of the larynx, had again considerably increased. Although he said that he felt much better, I had great doubts about the wisdom of letting him go into the country in this condition, and sent him to Mr. Butlin for a second opinion. He returned and told me that Mr. Butlin had at first sight said he would certainly have considered the larynx tuberculous, but that he had never seen a tuberculous swelling of this kind originate so suddenly. All the same, he thought it would not be wise for the patient to go into the country whilst in this condition. Upon this joint expression of opinion the country visit was given up.

In the course of the next week matters remained very much *in statu quo*. The patient was kept indoors, and for the first two or three days wore a Leiter's tube with ice-water round his neck. As this proved ineffectual to reduce the laryngeal swelling, repeated applications of mustard plasters were made to the neck, with no better result. He occasionally suffered from very slight pain in the left side of his throat, where the pharyngeal ulceration had reappeared, and from slight difficulty in swallowing. The actual conditions varied from day to day. One day the epiglottis was more swollen, next day the swelling had diminished, and the arytenoids, which on the previous day had been less swollen, had meanwhile become more oedematous. On one occasion he had slight disturbance in breathing in the evening, but this passed so quickly away that he did not think it necessary to send for me. Meanwhile the patient, although he would not admit it, became visibly depressed. Neither internal administration of iron and quinine nor the use of a spray of adrenalin and cocaine had any effect upon the local conditions. I did not dare at that time to give iodide of potassium on account of the laryngeal oedema, which I was afraid might be increased by the use of that drug.

On December 30th the swelling of the epiglottis was very much diminished, that of the arytenoids quite unchanged; fresh ulceration had appeared in the pharynx, this time on both sides symmetrically; the ulcer on the left side had again above it quite a lot of seriginous white opacities in the mucous membrano. Although the effect of the injections of a pneumococcus vaccine had not been a success in my first case, I suggested that Dr. Bulloch, who was a friend of the patient's, might be asked to prepare some such vaccine, and to this the patient, who had been all along desirous of trying this treatment, at once agreed. The same night when this was decided upon and previous to any vaccine treatment he had a slight rigor, followed by a rise of temperature to 101°. At the same time his throat felt very uncomfortable. This, however, passed off quickly, and the following morning he was none the worse for the attack. The epiglottis was less swollen that day, the pharyngeal ulcers were healing, and the oedema over the arytenoids was unchanged.

On January 2nd the patient, who had been seen on the previous day by Mr. Bowlby, who was a friend of his, was distinctly better. He could swallow more easily, had hardly any pain, and had had a good night, although the temperature on the previous evening had again risen to 100°. Dr. Bulloch informed me on that day that the swab which had been taken from the patient's throat contained various micro-organisms, with great predominance of pneumococci; that he had injected a rabbit and four mice with the culture, and that he was about to prepare a vaccine from it. On that day the oedema had quite disappeared from the epiglottis, the swelling over the arytenoids was much diminished, and the grey discoloration in the pharynx had given way to more natural colour, whilst the ulceration in that part had quite disappeared on both sides. The patient was allowed to take some warm food, was given a tonic, and permitted to take a little outdoor exercise, weather permitting.

It ought to be mentioned here that during the time the patient was in bed I almost daily carefully examined his chest without detecting the slightest evidence of disease.

His improvement continued during the next few days, and it was decided in consultation with Mr. Bowlby to grant the patient's urgent request, and let him go to Shanklin to recruit his strength, where he was to be under the care of Mr. Cowper. Now that the oedema had completely disappeared from the larynx, I gave the patient iodide of potassium as a matter of conscience, although there never had been any history nor any symptoms of specific disease. I may say at once that the drug had no effect whatever.

The reports from Shanklin were only moderately satisfactory. On January 18th Mr. Cowper reported that there had been a considerable amount of oedema of the uvula, and that after this had diminished the tumefaction of the epiglottis had returned, whilst small ulcers were now visible in the mucous membrane over the arytenoid cartilages.

On January 24th an inoculation was made of 7,000,000 pneumococci vaccine prepared by Dr. Bulloch. The patient's temperature went up to 101°, and he had several profuse perspirations, but the temperature next morning was normal, and Mr. Cowper reported that the whitish infiltration in the pharynx appeared diminished. A day or two afterwards, however, the throat began to feel more sore than previously.

On February 1st, 1909, I saw the patient again after nearly a month's absence. He came back looking very ill indeed, white and emaciated, with a pulse of 106, whilst his temperature was slightly subnormal. He told me that shortly after the injection of pneumococcus vaccine, nine days previously, his throat had been troubling him a good deal. On January 26th some ulceration had again appeared in his pharynx. This got worse during the next three days, and again three days afterwards the nurse found, in addition to the old ulcers on both sides of the pharynx, an ulcer $\frac{1}{2}$ in. deep on the posterior wall of the pharynx. There had also been considerable difficulty in swallowing and a good deal of pain. Three days before I saw him he had begun to improve a little, and at the time of the consultation he felt a little better on the whole. He himself attributed the aggravation to the vaccine injection.

On examination there were various fresh spots of ulceration on both lateral walls of the pharynx in the old situations, and another one further back on the left posterior pillar of the fauces. Further, there was a rather large but superficial ulcer on the posterior wall of the pharynx in the middle line below the uvula. The epiglottis was, if anything, a little less swollen than it had been when I last had seen him, but the arytenoid cartilages were not only fully as much tumefied as they had been during the worst stage before he left town, but were additionally all over superficially ulcerated, whilst the ventricular bands were either covered with some ashy-grey deposit or were infiltrated. Spraying with a glycothymoline solution did not alter the aspect. The vocal cords were free, and the voice was almost normal. The aspect of the larynx, however, was so typically tuberculous now that I proposed, and obtained, an immediate consultation with Dr. F. de Havilland Hall (also an old friend of the patient). Dr. Hall entirely agreed as to the tuberculous appearance of the larynx, and on joint examination of the chest we found some slight dullness posteriorly on the right side, corresponding to the spine of the scapula. In the same locality expiration was somewhat harsh, without any adventitious sounds being heard. We were much afraid that tuberculous infection had supervened, although, in view of the comparative novelty of the subject, we could not definitely exclude the possibility that a pure pneumococcus invasion might closely simulate a tuberculous affection. We agreed that, first of all, his expectoration should be repeatedly examined for tubercle bacilli and pneumococci, and considered, in the event of our suspicions of tuberculosis being corroborated, that a stay at a sanatorium would give the patient the best chance.

The bacteriological examination was made at the Laboratories of Pathology and Public Health, with the following result:

Tubercle bacilli are present in the sputum in small numbers: one small clump was seen. In a film stained by Gram's method there is a variety of micro-organisms present, many of them probably being derived from the mouth. Pneumococci are present in moderate numbers, and some short chains of cocci were seen.

This result was confirmed by a subsequent examination: On February 4th I made the following note:

The ulcer on the left side of the pharynx is distinctly more developed, and the two spots of ulceration have become confluent. On the right side the ulcer has again disappeared. On the posterior wall of the pharynx only the last remnants of the ulcer are visible. The left arytenoid cartilage appears to be much less ulcerated than it was, whilst the right is unchanged. The ventricular bands are less infiltrated, the vocal cords still free. Altogether a most perplexing case, the more so as his swallowing is much better, and as he has gained flesh. He does not now experience any pain on swallowing, which is, of course, quite against one's usual experience with tuberculous ulceration of the pharynx. On the other hand, his temperature goes up quite regularly to something like between 99° and 100° in the evening. Dr. Bulloch has examined his sputum yesterday, and whilst finding large numbers of pneumococci, could not satisfy himself as to the presence of tubercle bacilli. He is going to repeat his examination.

On February 6th, 1909,

The patient came, accompanied by Dr. Bulloch, who told me that all the mice which he inoculated with what he had obtained from the patient's secretion had died from general pneumococcus infection of the blood. The fact that they did not die so quickly as usual under such circumstances is due, in his opinion, first to the fact that in order to isolate the pneumococci he had to make a culture on agar, which probably diminished its virulence, and secondly, that instead of injecting the culture into the peritoneum, he injected it merely subcutaneously; but there can be no doubt that the patient's affection, in part, at any rate, is of a virulent pneumococcus infection, as I had suspected from the first.

On the other hand, in a very large number of examinations made on two subsequent days only four tubercle bacilli altogether could be discovered by him (Dr. B.), his assistant, and a third bacteriologist, so that whilst their presence cannot be denied, it certainly looks very much as if a tuberculous infection had become engrafted upon the primary pneumococcus infection. We discussed what should be done under the circumstances. Every form of treatment—sanatorium, tuberculin injections, local treatment—seemed rather hazardous and experimental in view of the double infection, and I proposed that a consultation should be held between Drs. Kingston Fowler, de Havilland

Hall, Bulloch, and myself before a definite decision was arrived at. To this Dr. Bulloch and the patient agreed. It was further arranged that previous to this consultation fresh specimens of the pharyngeal and laryngeal ulcerations respectively should be examined by Dr. Bulloch. On this day the pharyngeal ulceration on the left side looked quite unchanged. On the right side there are again some fresh epithelial opacities of irregular form, the ulcer on the right side has almost healed, in the larynx the ulceration of the arytenoid cartilage is distinctly less, whilst the swelling remains the same. The patient has distinctly less pain in swallowing, the temperature is normal in the morning, and goes up to about 100° at night; no cough, no expectoration.

On February 9th a consultation took place between Drs. Kingston Fowler, Hall, Bulloch, and myself, in which, later on, also Mr. Bowly joined. At the beginning of the consultation we informed Dr. Fowler of the history of the case, and Dr. Bulloch reported the extremely remarkable result he had obtained from the scrapings of the patient's pharyngeal and laryngeal ulcers which I had effected two days previously. Whilst the pharyngeal specimens were simply teeming with pneumococci without any evidence of tuberculosis, the scrapings taken from the ulcerated spots on the arytenoid cartilage contained large clumps of tubercle bacilli, sometimes 20 to 30 in one clump, such as are usually found only in vomicae, together with very numerous pneumococci. It seemed, therefore, quite evident that tuberculous infection had supervened upon the original pneumococcus infection. The patient's temperatures according to the latest charts show the characteristics of tuberculosis, being about normal in the morning and between about 99° and 100° in the evening. On joint examination of the pharyngeal and laryngeal conditions they were found to be very much as described in the last note. Even now it was curious how little the patient complained of pain and difficulty in swallowing.

The condition of the right lung had rapidly deteriorated since Dr. Hall's and my own joint examination; occasional crepitations were now heard in the suprascapular region on the right side, whilst the dullness extended to the apex of the middle lobe, and here also harsh prolonged expiration and occasional rhonchi were heard.

On discussing the case, we were unanimous in considering the prognosis as very bad, and we were also all of opinion that neither tuberculin injections nor local treatment of the larynx should be undertaken, but that the patient should go as soon as possible with his wife—who was throughout the bravest of comrades and the most devoted of nurses—to a sanatorium, where he should lead the ordinary sanatorium life, plus complete vocal rest. The patient agreed, and went a few days afterwards to the Cotswold Sanatorium, where during the remainder of his life Dr. Etlinger attended him with the greatest care and friendliest interest.

Unfortunately, the course of the disease throughout his stay, which lasted until his death on April 28th, was on the downward grade. At first, according to Dr. Etlinger's reports, there was a temporary slight improvement, the difficulty in swallowing being much relieved by applications of anaesthesia in the form of a spray, dissolved in palm oil. Local applications of nitrate of silver solution to the pharynx did not improve the condition.

On March 10th Dr. Etlinger reported that there had been a good deal of extension of the pharyngeal ulceration, which he then began to treat with applications of lactic acid.

On March 18th I went to the sanatorium to see the patient, who ever since his arrival, about a month previously, had been in bed with a temperature which lately had been varying between 100° in the morning and 102° at night. At the same time, his general health had kept up remarkably well, and, although he now had considerable difficulty in swallowing, he had actually gained 1½ lb. during the last week. His complaints referred particularly to pain in swallowing and to the difficulty of removing the abundant, extremely tenacious secretion from his throat.

On examining the pharynx I found it looking distinctly worse than when I had last seen him. The superficial ulceration and infiltration had so much spread to the right side that there was no longer any difference between the two sides. The uvula and posterior part of the gingivae had also become affected. The ulceration had not increased in depth, and the appearances now are those of a superficial white ulceration and infiltra-

tion with serpigineous edges, occupying the greater part of the soft palate, part of the uvula, the hindermost part of the gums, and—what is quite a new feature—the region of the lingual tonsil, where originally the whole affection had started. The larynx, which is not so much swollen as when I last saw it, shows the same appearance as that just described in the pharynx. The whole affection certainly does not look like an ordinary tuberculous affection. The conditions in the chest are very much the same as they were on the occasion of the last examination. There are no moist rales to be heard anywhere, nor has the dullness extended.

In the presence of Dr. Rupert Collins of Cheltenham, the bacteriologist to the Eye, Ear, and Throat Hospital there, I scraped the larynx, lingual tonsil, and pharynx, the scrapings being immediately transferred to culture tubes.

Dr. Collins's report was as follows:

From cultures made on Loeffler's blood serum, staphylococci and a small growth of pneumococci were obtained from the back of the tongue, whilst cultures made on agar-agar only showed staphylococci. The scrapings from the pharynx and base of uvula showed staphylococci and abundant growth of streptococci, whilst the cultures on agar-agar revealed similar conditions. The laryngeal scrapings on Loeffler showed a larger growth of pneumococci than that discovered in the scrapings from the back of the tongue, together with staphylococci and a small growth of streptococci, whilst on agar-agar staphylococci only grew. No examination was made for tubercle bacilli.

A subsequent report from Dr. Collins, dated March 24th, runs as follows:

Posterior Part of Tongue.—Scattered single and one large clump of tubercle bacilli, some pneumococci, and a few staphylococci and streptococci.

Pharynx.—A few tubercle bacilli and a few pneumococci.

Epiglottis.—Numerous tubercle bacilli, singly and in small clumps, numerous pneumococci, some staphylococci.

Sputum.—Numerous tubercle bacilli, a few cocci, and short bacilli.

It was evident from this that, as one would naturally expect, the two affections, which at first concerned different parts of the throat, as shown with such remarkable clearness by the result of Dr. Bulloch's examination on February 8th, should have become blended later on, seeing the close vicinity and constant opportunities of mutual infection.

From this time onwards a rapid deterioration in the patient's general health took place. The emaciation made constant progress and the temperature increased, so that during the last three weeks of his life it varied between 100° in the morning and 104° in the evening. On April 1st he was seen by Dr. Woods, of Dublin, who in a letter to me described the condition as one of great rarity.

On April 13th Dr. Etlinger reported that the difficulty in swallowing had greatly increased, and that this was probably due to the fact that the epiglottis had practically been destroyed by the disease. The patient continued to struggle on bravely against the disease. Some injections of tuberculin had been made by Dr. Bulloch's advice, but his temperature had been rather higher after them, and they were discontinued.

On April 22nd the report was that the patient had been losing ground rather rapidly, and that any chance of recovery was quickly disappearing. A patch of congestion was now noted at the base of the left lung.

On April 25th I went again to the sanatorium and found the poor patient in a very sad condition. Already on the previous day Dr. Bulloch, who had been to the sanatorium two days previously and had taken a swab from the patient's throat, informed me that this contained an enormous quantity of pneumococci and some staphylococci, whilst he had not examined for tubercle bacilli. On the other hand, Mr. Bowly, who had been to the sanatorium on the previous day, informed me on the morning of my journey that he had been surprised at the enormous improvement in the pharynx, and partly so in the larynx, but that apparently infection had taken place at the bases of the lungs, and that the breathing was very bad.

On my seeing the patient on April 25th I was shocked at the amount of emaciation which had taken place since I last had seen him. During the last three weeks his temperature had regularly varied from 100° in the morning to 104° in the evening. He looked very grey, and his lips were cyanotic; the respirations were 30 to 36 a minute, and the pulse 150 to 160. He had to be frequently refreshed with oxygen whenever his breathing got laboured. On the other hand, the improvement which had taken

place in the pharynx was simply astounding, and even more marked than I had expected from Mr. Bowby's report; practically all the ulceration which has been described on previous occasions had disappeared without leaving any scar. Only on the posterior wall of the pharynx there was still slight patchy ulceration. The epiglottis had for the most part been destroyed by ulceration, and the left half of the larynx was nearly immobile, but the laryngeal mucous membrane, which had been also ulcerated, had healed without showing much evidence of scarring. The pain in the throat had entirely disappeared, and the tenacious secretion which had for a long time been such a trouble to him was also quite a thing of the past. He coughed rather frequently, but not excessively so, and brought up white unmulmated sputa, which were not fetid and showed no traces of blood. The voice was very weak—almost reduced to a whisper.

On examination of the lungs both were found to be extensively affected; rhonchi and crepitations were heard everywhere, but more particularly over the bases of both lungs, where fine crepitation predominated over other sounds, and where marked dullness was found on percussion. There was no evidence of a cavity in these parts. The mechanical difficulty in swallowing was still great. He has so far taken a fair amount of nourishment, but has several times had attacks of choking, and Dr. Etlinger suspected that particles of food might during these attacks have entered the lower air passages, and have set up infective pneumonia (*Speisepestnemonie*), which is now present at the bases. I recommended rectal feeding, in addition to the food by the mouth, quinine and old brandy to be added to the nutrient injections, and hot poultices round the bases of the lungs.

On April 25th Dr. Mitchell Bruce went down to the sanatorium, and considered the case almost hopeless, but not absolutely so. He found the infection of the left lower lobe to be "massive" at that time, and considered it therefore not tuberculous, but due to pneumococcus infection of the nature of bronchopneumonia with pleurisy. He did not, as stated above, absolutely despair of the case, basing this slender hope upon the fact that, as the pneumococcus infection of the pharynx and larynx had yielded, there was a remote chance of the pulmonary affection doing the same.

By way of treatment he suggested regular saline injections, with brandy, to continue with food by the mouth, strychnine, and at night a little morphine with it, and of course continuation of oxygen.

Unfortunately, this treatment proved of no avail; the patient gradually sank on April 28th, and died very quietly in his sleep during the following night. No post-mortem examination was obtained. [2122]

Thus ended one of the saddest cases I have ever seen, and what one of his relatives wrote to me—namely, that "it seemed so hard, after so brave a fight, that all should end thus, but that the patient certainly had left behind him a memory of patient fortitude and heroic bravery, which surely must have left its influence on others"—is absolutely true.

Remarks.

The reason for describing the above case in such full detail is that pneumococcus invasion of the throat, and, more still, a combination of that disease with tuberculosis, is practically unknown. As a matter of fact, the various distinguished members of the profession who kindly lent their help in the management of the sad case, one and all stated that they had never seen anything similar. It seemed, therefore, desirable to assist further observers, and to enable them to build up a clinical picture of the disease, by describing the features of the first instance observed of such a combination in full detail. That the characteristics of pneumococcus invasion were blurred in the present instance by the supervention of tuberculosis there can be no doubt. When first the tumefaction of the larynx above described came into being, I anxiously asked myself whether it was possible that pneumococcus invasion of the larynx should thus mimic tuberculosis of that part, and during the whole remainder of the course of the disease it was a perfectly open question how much of the appearances seen in the larynx were due to tuberculosis, and how much to pneumococcus infection. On the other hand, there could be no doubt that the pharyngeal affection from first to last was

predominantly, if not exclusively, due to the pneumococcus invasion only. A proof of this is given not merely by the repeated bacteriological examinations, but above all in the fact that in the last four weeks before death occurred, the pharyngeal ulceration, which had been so long and so extremely troublesome, practically disappeared without leaving any loss of substance, a fact which is quite incompatible with the idea that the pharyngeal ulceration, too, might have been tuberculous.

One of the most interesting features is Dr. Bulloch's report, according to which the scrapings from the pharynx at one time yielded an almost pure culture of pneumococci, those from the larynx an equally characteristic culture of tubercle bacilli. This fact, I think, shows conclusively the mixed character of the infection, and, taken in conjunction with the course of the illness, demonstrates the fact that the tuberculous infection supervened upon the primary infection. Very interesting, too, is the fact that, whilst the affection clinically began as enlargement of the lingual tonsil, which for a time subsided, at a later stage of the disease ulceration and sloughing in that region occurred, and that the scrapings from the ulcerated surface in this region showed the presence of pneumococci.

With regard to the complications, which supervened later on, it is difficult, if not impossible, to say which part was played by, and how much of them was due to, each of the infecting micro-organisms. The first signs clinically observed in the chest were quite characteristic of ordinary tuberculosis. The later phenomena left it quite undecided whether the progressive changes were due to tuberculosis only, or to the combination of that disease with pneumococcus infection, whilst the final phenomena might have been caused either by "foreign-body pneumonia" (*Speisepestnemonie*) or by a sudden increase of virulence of the pneumococcus infection alone. The latter possibility finds support in Dr. Mitchell Bruce's statements.

I do not attach exaggerated importance to the statements of the patient himself, who dated the aggravation in the condition of his throat from the inoculation with pneumococcus vaccine, which was made on January 24th, but I can say positively that in this case, as well as in the first described by me, and in which also a pneumococcus vaccine was used, no improvement at all resulted from the employment of this method. The only remedy, in fact, of the very many which were used in the long course of this case which proved of any value were the anaesthesia insufflations, which, although they did not entirely abolish the difficulty in swallowing, yet materially alleviated the pain experienced during the act of deglutition. The effect of the remedy was not diminished by its long use.

It must be hoped that further contributions will shed more light upon the occurrence, pathogenesis, clinical features, and treatment of the disease, which, although hitherto undescribed, cannot be exceedingly rare, as is shown by the fact that in the course of three years 3 cases came under the notice of one single observer.

Remarks

ON

ACUTE PNEUMOCOCCUS INFECTION OF THE PHARYNX.

By JOHN ELLIOTT, M.D., F.R.C.P.,
HONORARY PHYSICIAN, CHESTER GENERAL INFIRMARY.

THE first three months of the present year have been remarkable for the prevalence of pneumonia in Chester and the surrounding district. So striking a feature has this been in my own practice that I have been at pains to ascertain from other medical men practising in the neighbourhood whether their experience has coincided with my own in this respect, and the replies I have received convince me that such has been pretty generally the case.

With a view to gain something like an accurate estimate of the number of cases I have, with the kind permission of Dr. Thomas (Medical Officer of Health for the city), examined the returns of deaths from pneumonia in the city of Chester during the first three months of each of the years 1905, 1906, 1907, 1908, and 1909.

It will be evident that there are so many sources of fallacy in such an inquiry—the prevalence at one time of measles with secondary pneumonia or broncho-pneumonia; at another time of whooping-cough; again of influenza—that one was not surprised to find the results confusing, and tending but little to elucidate the question of the incidence of pneumonia primarily due to pneumococcal invasion. Again, the varying severity and death-rate of any particular epidemic would render the mere enumeration of the number of deaths anything but an accurate estimate of the number of cases of the affection.

The figures, such as they are, are appended:

Deaths Returned either as "Pneumonia" or "Lobar Pneumonia."

January 1st to March 31st, 1905	...	2 cases.
" " " " 1906	...	8 "
" " " " 1907	...	10 "
" " " " 1908	...	3 "
" " " " 1909	...	11 "

It occurred to me that more useful information could be gained by finding the number of cases of acute lobar pneumonia which had been treated in the wards of the Chester Infirmary during the first three months of the present year. The cases had all been under the observation of one medical man—the house physician, Dr. Stanley Wood, who had every opportunity of judging of their applicability to such an inquiry, and to whom I am indebted for the return.

There were 28 cases of lobar pneumonia treated in the adult wards, and 5 in children under 5 years of age during the period January 1st to March 31st, 1909. Bearing in mind the fact that the hospital contains only 118 beds, including medical, surgical, and ophthalmic, and that the average number of beds occupied is 102, I think this is a convincing proof that pneumonia has been unusually prevalent during the period in question.

About the end of January I saw several cases of pharyngitis with fever and considerable enlargement of the cervical glands, the latter being a prominent feature of the cases.

The submaxillary lymphatic glands, the deep cervical glands under the sternomastoid, and also the glands below the lobule of the ear were enlarged, forming a mass which, in the early stage, might well lead one to make a diagnosis of mumps (an experience which fell to my own lot in one of my cases). The glands on both sides of the neck were enlarged, but more extensively on one side. The accompanying fever was not unusually high, 102° to 103°. The onset was sudden; the whole of the back of the pharynx was red, inflamed and swollen. Sometimes the tonsils were considerably enlarged, with follicular concretions visible. The fever was of short duration—about forty-eight hours usually, with slight rise of temperature in the evening for several days longer.

I was puzzled by the marked adenitis, which was quite unusual, and thought that probably influenza was at the bottom of the mischief. So far as my own experience went, however, the annual visitation of influenza had been delayed this year, and I had not then seen any cases of true influenza.

On January 25th my housemaid was taken ill with sore throat, with fever and glandular swelling. The attack after about a week culminated in a quinsy, which she had had several times before, and to which she was susceptible. Early in February another of the maids in my house was down with sore throat and adenitis, and then my four children were successively attacked. Meanwhile I awoke one morning myself to find my neck stiff and painful on one side with the glands under the sternomastoid swollen and tender. I had not been conscious of any sore throat. The soreness disappeared and the swelling subsided in the course of twenty-four hours, and then the same process

was repeated on the other side of my neck, to subside without further trouble in a day or so.

One of my children, a little girl aged 5, developed the affection severely. The whole of the pharynx was uniformly red and swollen, the glandular enlargement was well marked; the temperature 103°, with rapid pulse. The severity of the inflammation induced me to take a swab from the throat and inoculate an agar tube on February 24th. To my surprise I obtained a pure culture of the pneumococcus. The throat was painted frequently with a solution of mercury perchloride, 1 in 4,000; the inflammation began to subside with the fever, the glandular enlargement, however, continuing unchanged. In the course of a day or two the child had acute pain in the ear, with a fresh rise of temperature to 102°. An antiseptic dressing was applied to the ear to anticipate the abscess which was expected; it burst into the dressing; the pus was inoculated on an agar tube, and again a pure culture of pneumococcus was obtained. The same course of events followed in the other ear. The aural abscesses were treated with strict antiseptic precautions, and the discharge ceased in each case in about fourteen days. Hearing returned normally. The cervical glandular enlargement subsided slowly (as it had done in all the cases), and took a month or six weeks to disappear completely.

I took a swab from the throat of another of my children, aged 3, who was attacked by the pharyngitis, and found the pneumococcus in great preponderance, but mixed with a few staphylococci. In this case there was more marked affection of the tonsil, and no aural complications developed. In all other respects the case was similar. I exhibited Lumière coloured photomicrographs of the pneumococci, and also the growths on agar, at the meeting of the North Wales Branch of the British Medical Association at Colwyn Bay on April 20th. I saw other cases of the affection (13 in all) in which the main features described above were reproduced. Unfortunately, no cultivations were made, except in the 2 cases mentioned. There was no ulceration of the throat or

A. Injection of antistreptococcus serum 10 c.c., with the exception of 20 c.c. on December 9th.

membranous inflammation in any of them.

With regard to the origin of the affection I would sum up my conclusions as follows:

1. These cases were not influenzal in origin, for the usual visitation of influenza came later, and several of my cases afterwards developed influenza, which ran a typical course.

2. Although I could not trace exposure to infection from pneumonia in any of them, it was unusually prevalent at the time; indeed, my colleague and next-door neighbour, Dr. King, died of pneumonia on February 24th, at the very time when the cases described above were under investigation.

3. There can be no doubt that in the case of the two of my children from whom I took cultivations the infection was pneumococcal, and, taking into consideration the great similarity of the other cases, the remarkable glandular enlargement which was a feature of all of them, and the fact that the other cases in my own house were exposed to the same conditions as the two investigated, I think there can be little doubt that the pneumococcus was responsible for the trouble in all.

The following case, which I saw in December, 1908, with Dr. Storrs, of Overton (to whom I am indebted for some of the notes of the case), and Dr. Lloyd, of Chirk, must, I think, be classed as one of pneumococcal pharyngitis with general septicaemia.

F. H., aged 49, returned from a shooting box in Scotland in November, not feeling well; easily tired. December 1st, out shooting; felt ill, throat "rough." December 2nd, seen by Dr. Storrs; redness, covering the right tonsil; back of the pharynx swollen and red; temperature 101°; pulse rapid; temperature 102° at night. December 3rd, temperature 102°; inflammation spreading to left tonsil; whole pharynx in-

tensely inflamed and infiltrated; no membrane; not much glandular enlargement. December 4th, temperature 101.5; diphtheria suspected; 4,000 units antitoxin administered. December 5th, temperature still 101.5; 3,000 units given. December 6th, seen by Dr. Lloyd also; report on throat swab received, "No diphtheria"; urine nearly solid with albumen; pulse rapid and weak; temperature rose steadily. December 7th, temperature, at 10 p.m., 106; pulse 152.

December 8th. In the early morning a patch of pleurisy appeared on the right side. Seen by me midday with Drs. Scotts and Lloyd, the patient looked very ill, tongue dry and brown, slight herpetic eruption on the lips, uniform red glazed condition of the whole of the pharynx without either ulceration or membrane: at the right base a patch of dullness with bronchial breathing about 2 or 3 fingerbreadths in extent; no abnormal sounds of the heart; spleen not enlarged. We thought that in all probability it was a case of streptococcus infection from the throat. Ten c.c.m. of polyvalent anti-streptococcus serum were administered, and tubes of agar, galatine, blood serum, and bouillon (ten in number) were inoculated with blood taken from the median basilic vein at 7 p.m. On the morning of December 10th abundant growth of pneumococcus was found in all the tubes; meanwhile 20 c.c.m. of the serum had been injected on December 9th, and the patient's condition had improved materially: temperature and pulse falling, tongue becoming moister; taking well, sleeping quietly; 20 c.c.m. serum again on December 10th.

The daily administration of serum was continued with evidently good results. The albumen diminished in the urine until only a trace remained. The hypodermic administration of strychnine was pushed until twitching appeared. The temperature fell to 99° on the 15th, and we had great hopes of his recovery. The pulse, however, continued quick, and his exhausted heart began to fail on the 16th. Strophanthin and digitalin had been tried without success. He died on the 17th, with the usual premonitory rise of temperature, 105°. During the last few days of his life there was a hæmorrhagic punctiform rash on the thighs. The albuminuria increased again in the end. A sore on the shin from burn during a hot-air bath remained in an unhealthy condition covered with a greyish slough.

Although no cultivation was made from the throat, there seems to me every reason to conclude that the primary source of infection was in the pharynx, and that it was pneumococci. There was undoubtedly later a patch of bronchopneumonia at the right base, but it interfered in no way with the course of the case. There was neither cough nor expectoration at any time; the respirations were not quickened by it, and with the exception of the pleuritic pain which ushered in its onset its presence could only be ascertained by careful examination. It did not make its appearance until the main features of the case were well advanced.

The exact form which pneumococcal infection of the pharynx may take is still undetermined. Cornil described a case of abscess in the tonsil due to the pneumococcus; Jaccoud a case of pseudo-membranous pharyngitis of similar origin. Rendu and Bouloche¹ in 1891 recorded two cases of acute pharyngitis with sudden onset, accompanied by high fever of short duration, occurring in individuals who were exposed to pneumococcal infection, and slept in the same room. The pneumococcal origin of the infection was proved by inoculation of rabbits. In neither of these cases was there either ulceration or false membrane. In their main features they resemble the cases I have described above, but there was no great glandular enlargement.

In 1901 Monro² described a case of membranous pharyngitis which he considered to be of pneumococcal origin, as also have Bezanon and Griffin.³ The latter observers made use of the agglutination serum reaction to prove their case.

In the discussion which followed the paper by MM. Rendu and Bouloche (referred to above), Netter summed up the several types of pneumococcal angina as follows:

Suppurative) proved.
Pseudomembranous	
Follicular) doubtful.
Inflammatory	
Herpetic	

Recently (December, 1908) Sir Felix Simon⁴ described several cases of ulcerative pharyngitis with perforation of palate, and brought convincing evidence to show that they were pneumococcal in origin.

Observations

ON

THE THERAPEUTIC VALUE OF THE PNEUMOCOCCUS VACCINE IN THE TREATMENT OF PNEUMONIA

AND SOME OF ITS COMPLICATIONS.

BY A. BUTLER HARRIS, M.A., M.B. OXON.,

MEDICAL OFFICER OF HEALTH FOR THE LOUGHTON URBAN DISTRICT.

THE pneumococcus is, perhaps, next to the *coli* bacillus and the staphylococcus, the most constant parasite of the human race. Mackenzie¹ quotes statistics from various authorities, who state that 50 per cent. and upwards of normal individuals harbour this organism. "Hiss says it is more than probable that every individual acts as a host to organisms of true pneumococcus type at some time or other during the winter months, and probably at repeated intervals. The organisms leave the body with the saliva or sputum, and in either moist or dried sputum may remain virulent for a considerable time."²

That the pneumococcus of Fraenkel is the cause of pneumonia has been established since 1889;³ indeed previously, in the year 1886, he showed that a rabbit which had recovered from an attack of pneumonia was subsequently immune to a lethal dose of the organism.⁴ It is, therefore, unnecessary to burden the reader with what is now ancient history.

It may be taken as proved that practically every case of acute pneumonia is a case of pneumococcal septicaemia—that is to say, the infecting organism is not confined to local areas, but may be recovered from the blood.⁵ The crisis in septicaemic conditions, whether it be that of pneumococcus or streptococcus, is determined by the amount of protective material the invaded host is able to elaborate in a given time. When this elaboration is at a sufficient rate to inhibit the reproduction of the infecting organism, it is probable that the clinical manifestation of a crisis will occur. In 1891 the Klemperer brothers explained that the crisis in humans occurs at the moment when the poisonous products manufactured by the bacteria located in the lungs are present in the circulation in amounts sufficient to call forth in the tissues the reactive change that results in the production of the antitoxic substance which has the power of rendering the poison inert. To this end they prepared an antiserum, which they used in 6 cases. There was in 4 a temporary improvement, and 2 cases got well.

The Klemperers apparently did not realize that they were dealing with a general infective condition, and failed because their experiment consisted merely in the neutralization of a certain quantity of toxin.

The decade 1890-1900 may be described as the era of serum therapeutics, when antisera were used in many infective processes, but only attained success in that of diphtheria, a local infection producing a general toxæmia. In this connexion the names of Washbourne, Eyre,⁶ Pane,⁷ Wilson, Marchaux, Tyler, and Parr should be mentioned. Bokenham, indeed, showed that antipneumococcal serum had no bactericidal effect upon living pneumococci.

In the course of these serum investigations animals were necessarily inoculated with attenuated cultures, increasing in later inoculations in virulence. Foa discovered that animals thus immunized against one strain of pneumococcus were not necessarily protected against others, and Washbourne and Eyre⁸ found that Pane's serum protected against four out of five varieties, but not against the fifth. Here, then, arose a second factor, which militated against successful immunization at the bedside.

Wright's work on staphylococcal and tuberculin inoculations from 1902 onwards introduced the present era of vaccine treatment. He himself in his earlier papers argued that inoculation was indefensible in acute infective conditions, because of the probabilities of auto-inoculations. This supposition, based on the results

¹ Rosenow found pneumococci in 160 out of 175 in 1905; Fraenkel, found pneumococci constantly in the blood; Prochaski found pneumococci in blood of 50 consecutive cases, 1901.

obtained in tuberculous infections, rendered it extremely improbable that bacterial inoculation would be of any value in combating septicaemic conditions; in fact, such a course would increase the disaster.

The analogy, however, between tuberculous infection and an acute septicaemic condition is, happily, not a true one. In the former disease, when fulminating, necrotic foci are continually liberating dead organisms into the tissues, there to act as a bacterial vaccine. In pneumonia the bacteria are of a different type; they have not anatomically the same chance of getting into contact with the tissues, but remain in the lung, and circulate in the blood, until their life-history is done and they are digested. It may be that the spontaneous crisis in pneumonia and acute erysipelas may be due to some such process gradually building itself up.

With some such conception in his mind Macdonald⁵ studied the opsonic index in 8 cases of pneumonia, and found it low during the disease until the crisis was reached, when it suddenly rose as high as 1.6. He laid the foundation of vaccine treatment in pneumonia by producing artificial crises in rabbits infected with the pneumococcus by inoculating them with a vaccine made from the infecting strain. He was able at will to produce an artificial crisis, and recovery if he inoculated the animal with a vaccine made from the same strain with which it had been infected. Control rabbits, not inoculated, died. This research carried out in the bacteriological department of the London Hospital does not appear to have been followed up in hospital treatment.

Preparation of the Autogenous Pneumococcal Vaccine.

It is desirable to prepare the vaccine from cultures of the patient's own pneumococcus. If this is impossible, a stock vaccine made from a particularly virulent strain may be used.

It usually happens that the more virulent the pneumococcus, the more readily does it grow *in vitro*. On several occasions sufficient culture has been obtained after twelve hours' incubation from which to make the vaccine. The statement, therefore, which has been frequently made, that it is impossible to grow enough pneumococci to make a vaccine from in so short a space of time that it may be available, is untrue and misleading.

Pure cultures from chronic infections are difficult, and sometimes impossible, to obtain on account of rapidly growing contaminations. In acute pneumonia, however, if the rusty sputum be washed in sterile saline, and penetrated with a hot wire, a pure culture of the pneumococcus is, more often than not, obtained.

Agar-agar slopes should be used which have previously been smeared with a thin film of blood drawn from the finger. The latter should be washed, dipped in ether, and flamed. The ether flaming should be repeated three times. A narrow tape is wound twice round the end joint, and the skin deeply pricked with a sterilized needle or glass point behind the nail. Squeezing the pulp pumps out sufficient blood, which is then sucked up with a sterile Wright's pipette and nipple, and so conveyed direct to the agar slope. Three drops are sufficient, and if these be mingled with the water of condensation in the tube, a sufficient film can be spread by gravitation over the surface of the slope. For safety, the tube should be incubated for twelve hours before inoculation. It rarely happens, however, if this simple technique is followed, that any contamination with a skin staphylococcus occurs.

It not infrequently happens that sputum is not available. It is usually possible in acute pneumonia to recover the pneumococcus from the blood, if sufficient blood be drawn. This is most simply effected by passing the sterilized needle, attached to a large 20 c.cm. syringe (the "record" is, perhaps, the most suitable), into the median basilic

vein, already distended by compression, and withdrawing 10 to 15 c.cm. of blood; 5 c.cm. of 2 per cent. citrate in normal saline, previously drawn into the syringe, will obviate clotting.

The blood may then be introduced into ten agar sloped tubes. Sufficient growth will be obtained from the surfaces to prepare a vaccine without subculture. Care must be taken in both the above methods to keep the tubes upright and not to reflow the slopes with the blood which has settled at the bottom of the tube, otherwise it will be impossible to obtain clean emulsions of the pneumococcus for standardization.

CASE I.⁶

At Christmas, 1905, a lad named A. had a typical left basal lobar pneumonia. His crisis was unsatisfactory, and during January, 1906, he ran a variable temperature, normal or nearly normal in the morning, rising at night to 101° and 102°. There was a small dull patch at his left base, but there was no pleurisy. He was losing ground and weight week by week. His index to tubercle bacilli was normal, and the sputum contained none of these micro-organisms. There were, however, quantities of pneumococci present, and to these his index was low. He was inoculated towards the end of January with a pneumococcal vaccine made from cultures obtained from a case of chronic pneumococcal infection involving the knee-joint. This vaccine, although helpful in the case from which it was derived, had no effect on A.

In February, his condition becoming more serious from continued fever and loss of weight, he was seen in consultation with Dr. H. P. Hawkins. He agreed that probably there was a small consolidated patch at the left base, and that there was no pleuritic effusion. I suggested inoculating the lad with a vaccine made from his own strain of pneumococcus. After some little delay this request was granted. Within thirty-six hours of his inoculation all the usual clinical phenomena of resolution by crisis occurred, and the lad made an uninterrupted recovery. His index before the inoculation was 0.7, and at the crisis shot up to 1.4, whence it gradually declined to normal six days later. It occurred to me that possibly the introduction of the vaccine was coincident with the rupture of a small abscess. The microscopic character of the expectoration, however, negatived this, and later no physical signs were present to support this supposition. At the present time, three years after, the lad is perfectly well and has been in good health since his convalescence.

It would appear that the small dose of vaccine—50 million—was the determining factor in starting the sudden process of self-immunization into action.

CASE II.⁷

On April 30th, 1906, I was asked by Dr. Brooke, of Chingford, to see a case of pneumonia.

The patient, D., aged about 47, was a big man. He was seen on the fifth day of the disease. There was slight consolidation at the left base, definite peritoneal infection, distension of the bowel, effusion into his left ankle-joint, and thrombosis of his left posterior tibial vein. He was in a state of acute delirium alternating with dull apathy. His sputum showed pneumococci which grew rapidly on blood agar. His index was 0.4. A vaccine was prepared, and he was inoculated with 10 million dead pneumococci on May 2nd in the afternoon. Within thirty-six hours his condition began to improve, his peritoneal, stomach, and intestinal conditions were better, and the effusion in his ankle began to subside. His temperature did not, however, drop much until a second inoculation of 30 million was given on May 4th. Observation of his opsonic index taken twenty-four hours after the first inoculation showed that it had risen to 1.2, but by the time the second was given it had fallen again to 0.6. After the second inoculation his temperature fell from 102° to 99° on the morning of May 5th, rising during the day to 102°. He was accordingly inoculated again with 50 million in the afternoon of May 5th. His temperature fell continuously during the night and the whole of May 7th, rising on the morning of May 8th to 101°. It will be noticed that here the temperature became for the first time inverted, no doubt on account of the wearing out of the immunization. On the afternoon of May 8th he was inoculated for the fourth time with 50 million. On May 11th, 12th, and 13th, his temperature was normal in the morning, rising to 100° at night. During this time his mental condition varied between stupor and acute mania, and, indeed, this condition continued until about May 20th.

The sole remaining focus of infection was apparently in the left posterior tibial vein. On May 14th a fifth inoculation of 50 million was given. On May 15th his temperature never rose

Chart 1, Case II.—A. Abortive crisis relating only to lung; B. 30 million; C. 50 million; D. 20 million; E. 50 million.

above 98.8°. On the morning of May 17th he was not so well again, and his temperature rose to 99.4°. A sixth inoculation of 50 million on this date was given, and from now onwards it remained practically normal. A seventh and final inoculation of 30 million was given on May 22nd, and from that time he became himself. He made a perfect recovery at the time. At the end of last year (1903) he came to see me with a large ulcer in the lower third of his leg. This had gradually developed during 1903, no doubt due to the original blocking of the posterior tibial vein.

This case was clinically rather one of pneumococcal septicaemia, in which the lung infection was but a small incident. The pneumococcus was recovered not only from his sputum, but from blood drawn from his median basilic vein. The rapidity with which the graver signs of infection yielded to inoculation was remarkable, and I think that the fever was prolonged by the thrombotic condition of his left leg. It appears, too, that the septicaemic condition is not a contraindication for bacterial inoculation. As regards this point, Douglas* had successfully inoculated a case of acute septic endocarditis in the previous March (1905) with a streptococcal vaccine derived from the patient's own organism, which had been recovered from the blood. In March, 1903, a case of acute streptococcal septicaemia, with local erysipelas of the head and face under my own care, responded at once to inoculation. The temperature was 105°; there was low muttering delirium with subsultus, picking of the bedclothes; respirations were 40, and pulse 140. An inoculation of 20 million streptococci was given at 10 p.m., and during the night profuse sweating occurred. At 8 a.m. the temperature was 93.8°. No opsonic index was made.

CASE III.

Mr. W. A., aged 43, was seen by my colleague, Mr. G. L. Parsons, who has kindly furnished me with the clinical history.

On December 29th, 1907, he was feverish and slightly jaundiced. On December 31st he developed a cough in addition to the other symptoms, with viscid sputum and increased V.R. at the right apex. On January 1st, 1908, his liver was found to be enlarged, with pain and rigidity in the abdomen. There were definite signs of pneumonia at the right apex, with rusty sputum. On January 2nd the pneumococcus was observed in the sputum, and cultures on blood agar made. On January 3rd the patient sweated profusely; there was general improvement, and signs of resolution at the right apex. On January 4th he became worse; the pain and distension of the abdomen were more marked; there was evidence of infection of the left apex. On January 5th his pulse-respiration ratio was 2 to 1 or less; he appeared very emaciated and suffering from general toxæmia.

On January 6th the left apex and upper half of the left lung were consolidated. Pulse (120) feeble; respirations, 70; mental condition, excitable and delirious. The vaccine having been prepared, a dose of 60 million was given about 11 p.m. January 7th: Little improvement was noticed, and the dose of 60 million was repeated at 8 p.m., twenty-two hours after the first. The temperature fell two degrees that night. January 8th: There was marked improvement. The abdominal pain and distension disappeared, and the consolidation of the left lung began to resolve. The temperature rose one degree, but on January 9th fell to below normal.

Here again the septicaemic condition was arrested within twelve hours of giving the vaccine, though not until the second dose. At the bedside the case appeared to be hopeless, and the vaccine was given as a last resort. The intoxication was very profound, and it was not until January 12th or 15th that he recovered his normal mental state. The mental condition resembled that of Mr. D., periods of apathy alternating with an active fighting delirium.

He made a perfect recovery, and is now (1909) in good health.

CASE IV.

W. F., boy, aged 3½, also under the care of Mr. G. L. Parsons, was seen first on March 13th, 1908. He had been ill already for about ten days. His temperature was 102°. There was pain on the right side of the chest and poor expansion. There were some bronchitic sounds on both sides, and a patch of dullness with crepitations half way down the right side in the mid-axillary line. Complete dullness with loss of breath sounds at the right base. On March 15th there was some improvement in physical signs and symptoms. The temperature fell to 99° for the next two days. On March 18th the temperature rose rapidly to 103°. Pulse and respirations increased in frequency, and fluid in the right pleura extended high up. The urine became dark, and there was increased frequency of micturition. Total quantity passed was small; it contained albumen, pus, and casts.

On March 20th the right pleura was aspirated and found to contain pus. A film showed quantities of pneumococci. Cultures on blood agar were made with a view to the preparation of a vaccine. On March 21st the temperature rose to 104°; a portion of the seventh rib on the right side was resected and free drainage established. On the morning of March 22nd the temperature had fallen to 99°, and there was general improvement. On March 22nd the temperature was 99°. The discharge from the wound had become serous. More urine was passed, which was better in character.

On March 23rd there was constant cough, the temperature rising to 102°. The urine again became scanty and contained albumen; there was incontinence. The drainage tube was removed and the wound, which again had become purulent, was fomented. The temperature fell on the morning of the 24th, but again rose during the day. As the condition was now becoming very serious, 10 million of the vaccine, which had been prepared, was injected. The next morning (March 25th) the child's temperature was normal, but rose to 100° in the evening, and an injection of 10 million was given. There was marked general improvement.

On March 26th a third inoculation of a similar amount was given. The general condition had now improved; the wound discharge became serous again, and the urine, increasing in quantity, was free from albumen, blood, and casts. The pulse and respiration for the next two and a half days were normal.

On April 1st his temperature rose suddenly to 103°, the wound was found to be purulent, and the urine again became thick and contained albumen. Pulse and respiration were feeble and rapid. The right pleura was explored, a small pocket of pus evacuated, and a tube inserted again. An inoculation of 10 million was given. April 2nd. Temperature fell to 99° and under, but the wound still remained purulent. On April 4th the temperature rose to 101°, and another 10 million pneumococci was injected, as the urine was albuminous.

From April 5th onwards the temperature remained normal, the discharge became serous and gradually dried up. The urine gradually lost its albumen. To accelerate matters and prevent further flares of infection a further inoculation was given on the 6th. The child made a perfect recovery.

The influence of the vaccine was very noticeable, both on the discharge and on the urine, and it is remarkable how quickly so severe a pneumococcal nephritis, which was evidenced by the presence of blood casts and albumen, was each time checked and finally cured by inoculation. The rise

of temperature on April 1st and the subsequent fall was no doubt entirely due to the pocketing of a small quantity of pus, and it would be hardly fair to give any credit to the inoculation on that date beyond generally improving the whole resistance of the patient.

As in the other cases, the lung seems to have cleared without much difficulty and the gravity of the complications were the final factors to be reckoned with. No opsonic indices were done. It would probably have been better if they had, as thereby the various rises of temperature might have been prevented by earlier inoculation. Anyhow, this case illustrates very clearly that it is possible to give a child repeated inoculations at short intervals, the sole guide being the temperature. If we remember that

Chart 2. Case III.—A, Abortive crisis; B, 60 million, 11.50 p.m.; C, 60 million, enema; D, too delirious; E, 4.50 p.m.; F, 9 p.m.

Chart 3. Case IV.—A, Aspirated chest, pus; n, operation; c, wound fomented; d, injection of vaccine.

probably in all these acute conditions the rise of temperature is almost coincident with the fall of resistance, as has been shown by Latham⁷ in the case of pulmonary tuberculosis, the need for indices as a guide to inoculation seems in such circumstances unnecessary.

CASE V.

H. L., aged 36, under the care of Dr. Norman, was taken ill with left basal pneumonia on December 18th, 1908, at 1 a.m. The infection was of a very virulent type, and eventually extended to both lungs. He died on the morning of December 23rd.

I examined his sputum on December 18th, and found it contained many pneumococci and some *M. catarrhalis*. Cultures were made on blood agar, which grew with extraordinary rapidity, showing lanceolate, chain, and diplococcal forms. It was possible on December 19th to make 50 c.cm. of vaccine containing 80 million pneumococci per c.cm.

The first inoculation of 40 million was given on the evening of December 20th. "He was perspiring freely the first two days, and after the first injection it became more profuse, but otherwise there was no improvement in his symptoms, excepting the continual decrease in fever."

He was given a second inoculation on December 21st, and a third on December 22nd. After these two doses there was a slight rise, the temperature remaining at the higher level. "The abdomen was markedly distended, and, though there was no special vomiting or tenderness, I rather think he had peritonitis. He had a mottled, purplish rash over the abdomen and thighs not unlike that of typhus." There was albumen in the urine. The heart from almost the first became engorged and dilated, and Dr. Norman procured temporary relief by venesection.

A study of the temperature chart indicates that whilst possibly the first inoculation had some beneficial effect, the remaining two had none.

The remarkable rate of growth of the pneumococcus outside the body is an indication of its virulence.

CASE VI.

A. B., aged 60, labourer, was seen on December 27th. He had had a cough for a few days. His temperature was 102.6°, pulse 120, respirations 30. There was crepitation, bronchial breathing, dullness, and increased vocal resonance at the right base. His sputum was crowded with pneumococci. He was given 25 million of L.'s pneumococcus vaccine at 3 p.m. At 9 p.m. temperature was 103°, pulse 114, respirations 30. The consolidation had now extended to the middle lobe of the right lung. On December 28th, 10.30 a.m., temperature 103°, pulse 120, respirations 36, no further extension; 9 p.m., temperature 102.4°, pulse 120, respirations 40. December 29th, 11 a.m., temperature 102.3°, pulse 138, respirations 48; 11 p.m., temperature 102°, pulse 144, respirations 60. He was given 50 million of the same strain of pneumococcus vaccine. On December 30th the patient was moribund, and he died that evening.

In this case the patient was in a feeble state of health to begin with. The vaccine had no effect upon him, and he died of heart failure, the disease not extending during the last two days of his illness. Apparently, the toxic infection of his heart muscle, rather than a rapid extension of the disease, was the cause of death.

CASE VII.

Mrs. S., aged 63, was seen on March 27th. On March 26th she was seized with a severe bout of vomiting, and rapidly became ill. There was general bronchitis over the upper part of both lungs. There was consolidation of lower left lobe, with pain under the heart and failure of that organ. Ordered digitalis and carbonate of ammonia and brandy.

On March 26th the whole of the lower lobe of the left lung was solid. Temperature 100.6°, pulse 120, respirations 42. The pulse, though regular, was very feeble. The sputum was crowded with pneumococci; 25 million of L.'s pneumococcus vaccine was given. The heart did not respond in the least to stimulants nor to digitalis and ammonium carbonate, and she died at 8.30 a.m. the next day (March 27th).

The failure of the heart in this case was the cause of death, and the vaccine failed to produce the least result.

CASE VIII.

Mr. B., aged 58, a well-nourished man in good circumstances, had an influenza attack of the gastric type lasting from April 4th to 8th, but with no lung symptoms. On April 12th he was

seized with recurring rigors, and when seen had definite consolidation of the base of the left lung. Temperature 102.6° F., pulse 90, respirations 36. An inoculation of 25 million of L.'s vaccine was given at 6 p.m. At 10.30 a.m. next day he was breathing easily. Respirations 24, pulse 80, temperature 97.8° F. He had sweated profusely during the night. The left base was still slightly dull, but marked reduplications could be heard.

The crisis in this case occurred during the night, and after the administration of a vaccine obtained from a virulent fatal case (L.). It is reasonable to suppose that the vaccine was a factor in producing a crisis at so early a stage of the disease, between the second and third days at latest.

CASE IX.

W., female, married, aged 45, stated she had had attacks of asthma every winter, and for the last four winters this has been complicated with acute bronchitis. In the winter of 1906-7 *M. catarrhalis* and pneumococci were found in the sputum. Vaccines were made and used.

On February 17th, 1907, an inoculation of the mixed vaccine, 10 million of each, was given. The temperature dropped four hours after inoculation from 99.8° to normal. The cough became looser, and the asthma was relieved.

On February 21st the cough was dry and troublesome, the sputum contained few pneumococci, but many *M. catarrhalis*. An inoculation of the mixed vaccine was given as before. The next day the cough was looser again, but still paroxysmal; the index to pneumococci was 0.35.

February 25th, 26th, cough was more troublesome; the sputum contained chiefly *M. catarrhalis*; a few pneumococci. On February 27th, inoculation with *M. catarrhalis* vaccine from another strain (Addison), 0.5 c.cm., and

on February 28th cough much easier.

March 1st, cough worse; inoculation with Addison's *M. catarrhalis* vaccine 1 c.cm. March 2nd, cough easier. March 3rd, inoculation as before; had a good night. March 7th, improving; more pneumococci in sputum; gave 0.5 c.cm. of her own mixed vaccine. On March 8th the sputum contained less pneumococci and *M. catarrhalis*.

March 9th gave 0.5 c.cm. of her mixed vaccine; no cough.

From this time she remained fairly well.

During the following winter, 1907-8, she was under other care, and had no inoculations. There was a long period of several weeks of acute bronchitis with fever, and she did not really improve until the spring.

(On November 7th, 1908, she noticed a running from the nose; next day the nasal discharge was examined and found to contain practically a pure culture of *M. catarrhalis*. She had a bad cold in the head. Asthma developed two days later, and on November 12th the temperature rose suddenly to 102°. The sputum contained quantities of pneumococci and a few *M. catarrhalis*. Cultures and plates were made, and eventually a vaccine containing 160 million pneumococci per c.cm. was obtained.)

On November 14th, her temperature remaining up over 100°, an inoculation of 80 million was given. The temperature came down to 99.6° during the night; the expectoration was more abundant. On the evening of the 15th the temperature rose to 100.6°, and another 80 million were given. She had a good night, and on the 16th her temperature was 98.6°. The expectoration became rusty and abundant; the breathing deeper and easier. On November 17th, 18th, and 19th the temperature remained down; the sputum contained a few pneumococci and *M. catarrhalis*.

On November 29th there was an increase of catarrh with asthma; no rise of temperature. Sputum showed *M. catarrhalis* with a few pneumococci. Cultures were made. On December 2nd the nasal discharge showed *M. catarrhalis* alone. On December 6th an inoculation of a *M. catarrhalis* vaccine made from the above strain, 30 million, was given. Exacerbations of asthma were treated with the mixed vaccine on December 11th, 14th, 23rd, and 27th. In each case the asthma was relieved and the expectoration became looser and more abundant.

During January, 1909, she was practically free, only a few *M. catarrhalis* appearing in the sputum.

On February 2nd there was a slight return of asthma, and the mixed vaccine was again injected.

This case is interesting by itself. The details of two attacks in 1906-7 and 1908-9 are similar, as regards the infection, the necessity for frequent inoculation, and the results of the inoculations. The prevalence of the micro-organisms in the sputum has proved a very fair guide as to the variety of vaccine; and, indeed, this has been sub-

Chart 4, Case v.—A, 5 c.cm.; B, hypodermic injection of morphine; C, after washing; D, sponge; E, death.

stantiated in a number of catarrhal infections investigated. In the last attack very important evidence was obtained as to the rôle of the *Micrococcus catarrhalis* plays in these mixed infections. In this case the *M. catarrhalis* paved the way for the pneumococcus to become virulently pathogenic. In another case recently the *M. catarrhalis* was the forerunner of a general infection with the Friedländer pneumobacillus, and Allen and Benham both record cases of mixed infection also with *M. catarrhalis* and *B. septus*.

I think, perhaps, in both attacks a stronger vaccine of *M. catarrhalis* might have been used; but in this case it was difficult to grow enough at one time. In the second attack the inoculation of December 16th produced a definite resolution sputum with a fall of temperature to normal—phenomena similar to cases of a definite lobar type.

CASE X.

T. P., aged 58, male. Gave on September 17th, 1908, a history extending over several years. He had been liable he said to repeated attacks of nasal catarrh, with loss of smell and taste. Latterly these had been more severe; the bronchial tubes had become affected, and he had several times been laid by with jaundice and catarrh of the stomach. Extreme prostration and muscular weakness followed after an attack. Cultures made from the nasal and purulent discharge showed *M. catarrhalis*, Friedländer's pneumobacillus, *Streptococcus*, and a few lanceolated pneumococci in pairs. Vaccines were made of *M. catarrhalis* and Friedländer, and were given during the next three weeks with little result. The indices to Friedländer were normal. On October 14th, 1908, he started a fresh cold. Cultures of the sputum were made on blood agar on the 17th, and showed more pneumococci, but a preponderance of Friedländer. More Friedländer vaccine was given, with the result that this organism was wiped out of the sputum, and on the 23rd the sputum apparently contained only pneumococci. Cultures on blood agar were made and a pure strain of the true pneumococcus obtained; a vaccine was made from this, 95 million per c.c.m. in strength. On November 4th he had more or less recovered from this cold, and his index to the pneumococcus was 1.7. He was inoculated with 50 million pneumococci.

On November 7th his index for pneumococcus was 2.2; sputum of the 8th contained pneumococcus, *M. catarrhalis* and *B. septus* in the shed mucous epithelial cells, as well as Friedländer. On November 11th he was inoculated with 50 million pneumococci. His index to pneumococcus was 2.0. On November 14th the sputum was less, thin, and clear, but contained all the above micro-organisms. For the first time his general condition was better. He coughed less and was more vigorous. His appetite was returning and his colour improving.

I determined, as my results with *Micrococcus catarrhalis* and Friedländer vaccines had been negative, and as he had obviously improved after two inoculations with the pneumococcus vaccine, to continue the latter, particularly as in this organism alone he had shown an index differing from the normal. Inoculations were given on November 25th, December 3rd, 14th, and 23rd. During this time he remained free from catarrh, and was in excellent health and spirits. He expressed himself as being in much better condition than he had been for several years, although he had been working the whole time at high pressure in the city. During January, 1909, he was so well that inoculations were unnecessary.

On February 2nd, 1909, the sputum was rather thicker and more abundant. It contained *M. catarrhalis*, pneumococcus, *B. septus*, and Friedländer's pneumobacillus. The *M. catarrhalis* was in large amount. As severe colds had been going through his office, and from other sources I was aware that there was an epidemic of *M. catarrhalis* abroad, I gave him 125 million of a *M. catarrhalis* vaccine.

This case illustrates the feeble toxicity the pneumococcus may assume. Apparently it was doing little in the respiratory tract, but was probably the cause of his malaise, recurrent jaundice, and bilious attacks. I have little doubt (though the evidence is by no means conclusive) that the pneumococcus was the chief offender, because it was a matter of common remark how his colour, energy, and elasticity of spirits returned after the second inoculation with the pneumococcus vaccine. It will, however, require at least a year's careful observation in this case to settle definitely the etiology. Meanwhile it is worth recording this history in the present series of cases of pneumococcal infection.

CASE XI.

Mr. C., aged 50, was sent to Harrogate in the spring of 1908 for intractable gout, to be under the care of Dr. Wesley Smith, who, however, from the history suggested an infective process, and advised a bacteriological investigation.

On May 13th, 1908—Twelve months ago Mr. C. had pneumonia, and got better, but a chronic cough remained; the lung has cleared up except a small patch at the left base. Before the pneumonia he had a cough with pus, I believe, but was always able to work. Just over a month ago (April 1st, 1908) the left leg began to swell, which looked like an acute attack of gout,

but there was very little redness in the ankle; fluid in the left knee joint; no temperature. He was anæmic. There is a slight systolic tricuspid murmur. He feels well in his body, gets up every day, and goes out in a chair."

May 17th. His sputum was sent to the Clinical Research Association. A pneumococcus was isolated and subsequently sent to me.

I saw him myself on May 19th. He was lying in bed pale and anxious, breathing quickly, with a rapid pulse. The heart was irritable, with a definite local murmur. There was a trace of slight dullness at the vocal resonance over the right middle lobe behind, and definite dullness over the left base. The expectoration was abundant and purulent.

His left leg was oedematous and painful, particularly in the ankle; there was fluid in his left knee. I came to the conclusion that he was in all probability suffering from a prolonged pneumococcal infection widespread in character. His temperature in the afternoon was over 100°. The opsonic indices of specimens of his blood proved instructive.

The blood index for May 19th was 0.71 against the pneumococcus; on May 21st, 0.88; and on May 23rd, 1.0. On this date he was said to be improving; the oedema fluid from the leg gave an index against the pneumococcus of only 0.09.

The use of Bier's passive congestion method by placing a rubber bandage lightly round the upper part of the thigh for twenty minutes daily was advised, and a course of inoculations with a pneumococcus vaccine as soon as it could be prepared. The Bier's treatment was begun at once, and within two days the leg began to go down, the general condition to improve, and the sputum to decrease.

The first inoculations of 30 million pneumococci were given on June 1st and on June 7th. On June 8th, sputum still less, sweating had stopped, but the anæmia was still severe.

On June 17th a third inoculation was given. Dr. Wesley Smith reported: "Mr. C. is a little better. The left leg, which was so swollen, has gone down, and the right leg is now going down. I am keeping him in bed. For a week the sputum has changed in character—instead of being yellow, it is now merely grey mucus, and only one lump every other day. His lung is much better."

The inoculations were continued at intervals of seven days. On July 7th Dr. Wesley Smith writes: "The mucus now contains no pus; the temperature rises to 100° at night, and is 97° in the morning, but sometimes is normal in the morning. The legs are as swollen as much as before."

The inoculations, etc., were continued as before, but with an increased dose of 250 million. On July 23rd Dr. Wesley Smith writes: "Mr. C. is getting better. I am sure the vaccine has set him up and done him a great deal of good. The anæmia is getting better. He is gaining flesh, sleeps well all night. The fluid in the knee is gone, and the oedema in the ankles and legs is much better, but the latter are still swollen. The systolic murmur at the base is gone." The larger amount of vaccine was still continued.

On September 12th the doctor reports: "Mr. C. has greatly improved. The sputum is now like grey mucus, and only comes in small quantities. The temperature rises to 99° every night, instead of 100°. He is no longer anæmic. There is only the faintest trace of endocardial murmur. He has got fat. His legs are still swollen. I have just begun the Bier's treatment again. I left it off until now, because he said it upset him, but it does not do so now."

Mr. C. slowly recovered, and returned home early in December.

The points of interest in this case are that he recovered in six months, although he had been infected for a year previously; that, although his joints were probably infected with the pneumococcus, there was no suppuration; that he began to improve generally directly the Bier's treatment was begun, suggesting that this method actually produced auto-inoculation; that his immunizing power gradually returned, wiping out the general infection; and that this was slow, owing to the feeble anæmic state he had got into from the prolonged toxæmia.

Latham^{9, 10} in the discussion on pneumonia at the Medical Society of London, March, 1908, stated that he believed that in the near future a great advance might be made by the adoption of vaccine treatment. The lung tissue had some peculiar power of resistance to the pneumococcus, for an abscess of the lung, as the result of pneumonia, was very rare, whilst in other situations the pneumococcus frequently led to abscess formation. This fact encouraged the belief that vaccine treatment might be of great service. The results of vaccine treatment obtained by Roelke, in a few cases of severe pneumonia, and one case of pneumococcal endocarditis were most encouraging. The results of vaccine treatment in case of delayed resolution of the lung, and in pneumococcal infection of other portions of the body were also most encouraging. In 2 cases of pneumonia he (Latham) had recently administered dead pneumococci by the mouth, and in both cases this was followed by a marked fall in the temperature which was progressive, in one case on the third day, and in the other on the second day.

Floyd and Worthington¹¹ record the following cases of pneumococcic empyema treated with a pneumococcic vaccine:

A girl of 2 years entered the Children's Hospital, Boston.

February 19th, 1907. For eight days previously there had been pain in the right side. On the day before admission the skin broke on the right front of the chest and considerable pus discharged. On the day of entrance a portion of the eighth rib was resected and a few ounces of pus evacuated. The child was thin and weak and in a precarious condition.

February 22nd. Culture from discharge showed pneumococci. Index to the organism was 0.6. A stock vaccine was used and 50 million organisms given.

February 23rd. Index 0.25.

February 24th. Index 1.17.

February 25th. Index 2.25, child brighter, sinuses discharging freely.

February 26th. Inoculated 50 million organisms.

February 27th. Index 0.69.

February 28th. Index 2.14. Discharge lessening. Eating better.

Decidedly stronger.

March 1st. Inoculated 50 million organisms.

March 2nd. Index 1.38. Gaining daily. Inoculations were continued regularly, and the child gained rapidly. After about three weeks she went to the country with no discharge from either sinus and in excellent condition.

A boy of 3½ years entered the Children's Hospital on February 15th, 1907. There was a history of pneumonia, with a crisis of five days previous to entrance. This was followed by a second rise of temperature, and a diagnosis of empyema was made. The portion of the eighth rib in the posterior axillary line was resected and about a quart of pus evacuated. A culture showed a pure growth of the pneumococcus present.

February 18th. Osmonic index 1.1.

February 19th. Patient inoculated with 50 million pneumococci.

February 22nd. Index 1.59.

February 23rd. Index 1.5. Inoculated with 50 million organisms.

February 24th. Index 0.45. The child was restless following the last inoculation, and the temperature rose to 105°.

February 28th. Index 1.2. Temperature still elevated, but general condition improving.

March 1st. Index 0.72. Inoculated with 50 million. Discharge slight, and there has been a steady gain in weight and strength.

March 5th. Temperature normal; general condition good.

March 7th. Index 1.2.

March 13th. Index 2.0. Very slight discharge from sinuses. Up about the ward. Fairly well. The general gain continued and the sinus closed rapidly. Child sent to the country for a few weeks.

A girl of 3 years entered the Children's Hospital on February 25th, 1907, with signs of infection on right thigh. The following day an incision was made and about 1 oz. of pus evacuated from the femur. A culture from the wound showed the pneumococcus.

February 28th. Index to pneumococcus 0.71.

March 1st. 50 million pneumococci given.

March 4th. 50 million pneumococci given.

March 8th. Index 1.1. Condition of wound much improved; very slight discharge.

March 10th. Incision closing rapidly; no discharge.

March 19th. Wound healed solidly. Child sent home well.

The criticism which presents itself in the two cases of empyema, is that in both cases sufficient time was not given after operation to see the effect produced by the evacuation of the pus and the consequent autoinoculation which invariably takes place under such conditions. In the first case the index was 0.6 two days after inoculation, probably indicating a negative phase. This interpretation is supported by the fact that a fall to 0.25 was registered the next day, intensifying the general low bacteriostatic pressure. That the index rose rapidly is not surprising, but since the first dose produced so marked a negative phase in this case it should certainly have been reduced in the second inoculation. It was not, with the result that a profound drop from 2.25 to 0.69 was produced. In the second case, on the second inoculation of 50 million, a deep negative phase from 1.4 to 0.45 was produced, involving a rise of temperature, which lasted several days. There is no evidence on paper that this child would not have done perfectly well without special inoculation, and the notes show that there was actually a set-back caused by inoculation of what certainly in this case seemed to be too large a dose. My own experience is that 10 to 20 million of this vaccine is quite sufficient for a child. It is to be regretted that the temperature charts were not given in the reports.

The third case was certainly one for inoculation. These infections of the thigh, so common in young children, and so often associated with the lower epiphysis of the femur, yield quickly to the effects of inoculation if given after the disturbance caused by the operation has passed off.

CONCLUSIONS.

It may be taken as a clinical fact that in pneumonia death usually takes place through failure of the heart. Particularly obvious is this in the cases of virulent pneumonia, where death occurs about the fourth day of the disease. Jørgensen aptly says, "It is the heart, and always the heart, upon which the burden is ultimately thrown. Death results from the insufficiency of the heart."¹² It is easy to understand, therefore, why in virulent pneumonia

with early heart failure the vaccine treatment in many cases, though it may produce a fall in the temperature, fails. The toxæmia produced is already too profound for just the arrest of the infecting process to be successful. It would seem logical that scientific treatment demands not only the exhibition of the vaccine as early a stage as possible, before an overwhelming toxæmia has occurred, but also the introduction of a sufficient quantity of an antitoxin at the same time. I am not aware that any work has been hitherto carried out on these lines—the employment of both vaccine and antitoxin—at the same time.

It is not improbable that, in the case of the pneumococcus, the success of a vaccine is not simply due to the fact that it should be autogenous. A good deal of stress is laid upon this feature; but the fact of a vaccine being autogenous narrows down the issue to (1) the right organism being selected, and (2) the vaccine being prepared, if not unduly subcultured, from an organism of requisite virulence.

Fraenkel's pneumococcus is, however, as far as we know, invariable; it is not like the streptococcus (Gordon), an inclusive term for several varieties. On the other hand, we know from the staphylococcus and *coli* bacillus that these may be so subcultured as to lose their original virulence, and that vaccines so prepared are of little use therapeutically. If, then, a potent and reliable stock pneumococcus vaccine is to be obtained, it should be made from as virulent a strain as possible. There is unhappily no difficulty in the early months of the year in obtaining as much as is wanted. The truth of this argument can only be verified by a great number of observations. My own results, as far as they have gone, certainly tend to support this view.

With regard to the treatment of acute pneumonia by inoculation, the practical conclusions which alone can interest the busy clinician are:

1. That successful inoculation for pneumonia is possible.
2. That inoculation does no harm.
3. That a vaccine from one or a number of virulent strains should be used.
4. That it should be introduced as early as possible.
5. That the estimation of the opsonic index is not necessary.
6. That the observation of the temperature and physical signs is in pneumonia a sufficient guide in gauging the repetition of the dose.

Infections of the lung by the pneumococcus which fail to resolve after an acute pneumonia, as well as pneumococcal infections of other areas, ought certainly to be treated with a pneumococcic vaccine; and these cases appear to afford a reasonable prospect of success.

To place the whole question on a sound scientific basis needs, however, a vast inquiry by many workers. It was thought, however, that the above observations were worth recording, as helping in some small measure to clear the ground, and so indicate the direction of a research which has already lagged behind all too long.

REQUESTS OF £5,000 to St. Bartholomew's Hospital and of sums of £500 each to the Kensington Dispensary and Children's Hospital and the Home for Confirmed Invalids, Highbury, are contained in the will of the late Mrs. Holborn, of Campden Hill, who died on April 28th.

The French Surgical Association will hold its twenty-second congress in Paris next October, under the presidency of Dr. G. Richelot, surgeon to the Paris hospitals. The opening meeting will take place on Monday, October 4th. The following questions are proposed for discussion: (1) Surgery of the arteries; (2) care of the patient before and after abdominal operations; (3) surgical intervention in injuries of the spine and spinal cord. An exposition of surgical instruments, illuminating apparatus, and dressings will be held during the congress. The General Secretary of the Congress is Dr. Walther, 68, rue de Bellechasse, Paris (7c).

The Croonian Lectures

ON

RADIO-ACTIVITY AND CARCINOMA: AN EXPERIMENTAL INQUIRY.

DELIVERED BEFORE THE ROYAL COLLEGE OF PHYSICIANS OF
LONDON IN JUNE, 1909.

BY W. S. LAZARUS-BARLOW, M.D., F.R.C.P.,
DIRECTOR OF THE CANCER RESEARCH LABORATORIES, THE
MIDDLESEX HOSPITAL.

LECTURE III.

THE ELECTRICAL PROPERTIES OF RECOGNIZED RADIO-ACTIVE
SUBSTANCES; OF NON-MALIGNANT TISSUES; OF CAR-
CINOMATOUS MATERIAL; AND OF CERTAIN SUBSTANCES
COMMONLY SUPPOSED TO BEAR A CAUSAL RELATION TO
CARCINOMA.

THE researches to which I am now about to refer have been in progress for the past three and a half years nearly continuously. This length of time was necessitated partly by the importance of controlling certain of the results, but mainly by the fact that the differences between the control and the experimental conditions are so small that special care was necessary for their determination. The rate at which the electricity on charged gold leaves leaks from them is dependent upon so many factors that unless the extrinsic causes of leak are reduced to the lowest possible point small intrinsic differences are entirely lost sight of. Electroscopes in which the natural leak is greater than about 1 mm. per hour are quite useless for the purpose; in the majority of the cases the charged leaves approximated over a fixed distance at a rate of about 0.6 mm. per hour, and in a large number the rate was about 0.2 mm. per hour. It follows that the length of time necessary to obtain a single observation, whether control or experimental, is considerable; in no instance has it been possible to obtain more than one observation a day, and in certain of the experiments it took two days to obtain each observation. This difficulty was obviated to some extent by using several electroscopes. As a rule two control electroscopes (charged + and - respectively), and eight experimental electroscopes (four charged + and four charged -) were under observation.

It is unnecessary to enter here into a description of the apparatus or of the precautions taken; they are sufficiently described elsewhere.* Similarly, it is unnecessary, in the majority of cases, to refer to the actual experiments. It will suffice to state that the object of the research was to determine whether the leak of a fully earthed lead electroscope differed according as it did or did not contain one of the substances under investigation.

The substances examined were: Liver, kidney, lung, and spleen (four specimens of each) from non-malignant cases; four specimens of hepatic substance from livers the seat of carcinomatous metastasis; four specimens of the inorganic constituents of bones from non-malignant cases; four specimens of the inorganic constituents of bone from cases of carcinoma, in one of which the bone itself was the seat of secondary growth; twelve specimens of carcinoma. Of substances supposed to be causally related to carcinoma, the following have been examined electrically: Three samples of clay pipe, each sample consisting of portions of three distinct pipes from different sources,

powdered and mixed; two samples of soot; one sample of impure cholesterol gallstone from a case of columnar cell carcinoma of the gall bladder; one "pure" cholesterol gallstone; "pure" pigment gallstones; four samples of pitch from different localities; three samples of paraffin wax; three samples of betel nut; and one sample each of metallic arsenic, arsenious oxide, and coal.

In addition to the above, experiments have been carried out in connexion with the recognized radio-active substances—uranium, thorium, and pitchblende—in order to throw light, if possible, upon certain unexpected electrical phenomena.

In the case of the carcinomatous material diagnosis was always made microscopically. Four cases were primary (cervix, cervix, tongue, breast), and 8 metastatic. Of the latter, 6 came from the liver, the sites of the primary growth being rectum (3 cases), breast (2 cases), stomach (1 case); the remaining 2 were pulmonary metastases from cases of mammary carcinoma. The substances were introduced into the electroscopes in the dried powdered state to which they had been reduced for skotographic examination.

RESULTS OF EXPERIMENTS.

In the case of carcinoma material which has been extracted with water and subsequently with ether, or has been extracted once and for all with acetone, there is strong evidence that the leak of the electroscope is accelerated, whether the charge on the leaves be + or -. Similarly there is evidence that the inorganic constituents of bone, whether taken from non-malignant or from carcinomatous cases, accelerate electroscopic leak, whether the charge on the leaves be + or -. And, thirdly, clay-pipe, and possibly one sample of soot, acted in an identical manner.

So far, therefore, there is evidence to satisfy the physicist that the substances mentioned above are "radio-active" in the physico-chemical sense of the term. But already difficulties have arisen, for whereas the carcinomatous material produces skotographic effects when it has been extracted with water alone or with ether alone, it fails to do so when it has been extracted with both, or with acetone, while the inorganic constituents of bone and the clay pipe are equally non-skotographic.

The difficulty becomes much greater, however, when it is found that substances exist which, so far from accelerating the discharge of the electroscope or being without appreciable effect, actually retard the leak whether the charge on the leaves be + or -. I make this statement with a full sense of the responsibility I am incurring. I am aware that the physicist does not recognize such retardation or "antiradio-activity" as it may be termed. I am aware that it includes theoretical considerations of great magnitude, that if recognized radio-activity means the breaking up of large atoms into smaller ones antiradio-activity may mean the synthesis of elements with high atomic weight from elements with lower atomic weight. But I have carried out the experiments with the utmost care of which I am capable, and have found evidence of antiradio-activity a sufficient number of times to be convinced of the accuracy of my observations. Moreover, as the following experiments will show, I believe that evidence of antiradio-activity may be obtained by the use of recognized radio-active substances themselves.

If an aluminium disc be kept in close proximity but not in contact with uranium or thorium or pitchblende for forty-eight hours under fully earthed conditions and its influence upon electroscopic leak after such exposure be compared with its influence before exposure, it will be found, I believe, that the rate of leak has become retarded. This retardation persists for many days, and is independent of the sign of the electricity with which the leaves are charged. Full details of the experiments are given elsewhere.† It will suffice to give here a summary of the results obtained in an experiment lasting over four months, and carried out in order to reinvestigate the question, owing to the adverse criticism to which the first set of experiments had been exposed. This second experiment completely confirmed the first.

* Archives of the Middlesex Hospital, vol. vii (Fifth Cancer Report), 1906, p. 190. In this article and in articles that have appeared in the Sixth and Eighth Cancer Reports (1907 and 1909) full details are given of the experiments upon which the conclusions referred to in this lecture are founded.

† See previous footnote.

Experiments showing that an aluminium disc which has been kept in proximity to a recognized radio-active substance has acquired retarding or antiradio-active properties on electroscopic leak. The values are the mean differences between the experimental and the control electroscopes (Cf. "Arch. Middlesex Hosp.," vol. xii, 8th Cancer Rep., 1909, p. 145).

Experiment.	Control Period.	Blank Experiment.	Actual Experiment.	Remarks.
I. Electroscope in which was examined the aluminium disc placed in proximity to uranium nitrate	Mm. -25	Mm. -25	Mm. -27	29 observations for retardation to 10 for acceleration.
II. Electroscope in which was examined the aluminium disc placed in proximity to uranium oxide	+86	+85.5	+82	36 observations for retardation to 9 for acceleration.
III. Electroscope in which was examined the aluminium disc placed in proximity to pitchblende	-18	-21.5	-26	44 observations for retardation to 2 for acceleration.
IV. Electroscope in which was examined the aluminium disc placed in proximity to thorium	-31	-34	-38.5	37 observations for retardation to 9 for acceleration.

NOTE.—In the case of thorium the observed acceleration occurred on the first four days of each of the two parts of which the actual experiment consisted and was evidence of the well-known "induced radio-activity" due to thorium.

The following experiment shows that a similar retarding property is conferred upon an aluminium disc that has been placed in proximity to a substance that itself has retarding influence upon electroscopic leak. This experiment was carried out at the same time and under the same conditions as those mentioned above.

Experiment.	Control Period.	Blank Experiment.	Actual Experiment.	Remarks.
V. Electroscope in which was examined the aluminium disc placed in proximity to a cholesterol gall stone	Mm. -5	Mm. -4	Mm. -8	41 observations for retardation to 5 for acceleration.

Returning now to a consideration of carcinomatous material itself, it appears that the electrical properties differ according as the substance has or has not been extracted before its influence upon electroscopic leak is determined. Moreover, the extract exerts a definite influence upon the leak, and that influence is in the opposite direction to that exerted by the extracted substance. This is shown by the following table, condensed from one given by me elsewhere¹:

Table showing the influence upon electroscopic leak of four specimens of carcinomatous material before and after extraction and of the extracts themselves.

	I.	II.	III.	IV.
Charge on gold leaves	- +	- +	- +	- +
Carcinoma, dried and powdered	A A	B? O	A O	A O
Above after extraction with ether	A A	R A	A A	A A
Above after extraction with ether and subsequent extraction with water	A A	A A	A A	A A
Ethereal extract of above...	R R	R R	R R	R R
Watery extract of above after its extraction with ether	R R	A? R	A R	R R

A is used to signify acceleration; R, retardation.

The manner in which the uncertain influence upon electroscopic leak exerted by the substance when simply dried and powdered gives place to an increasing evidence

for an accelerating power after each extraction; the power fully retarding character of the first extract, and the less powerful but still distinctly retarding character of the second, afford a chain of evidence, not only for the existence of "antiradio-activity," but also for the presence of both forces in carcinoma tissue, that cannot lightly be dismissed. So far as concerns the accelerating influence of carcinoma material after extraction, the conclusion given above is supported by the results of examining electroscopically eight other specimens extracted with acetone.

While carcinoma tissue after extraction accelerates the leak, this is not the case with liver or lung from non-malignant cases. These extracted tissues were found uniformly to retard leak. The acetone extract of non-malignant liver, however, agreed with that from carcinoma tissue in retarding leak, and the unextracted tissue showed a less tendency to induce retardation than the extracted. Below are given the results obtained with four specimens of liver from non-malignant cases.

Table showing the influence upon electroscopic leak of four specimens of liver from non-malignant cases before and after extraction and of the extracts themselves.

	OTI I.	II.	III.	IV.
Charge on gold leaves	- +	- +	- +	- +
Liver, dried and powdered.	A R	R? R	R R	R R
Above after extraction with acetone	R R	R R	R R	R R
Acetone extract	R R	R R	R R	A A?

A signifies acceleration; R, retardation.

In the first lecture evidence was given to show that the skotographic action of an organ which is the seat of carcinomatous metastasis differs from normal. Examination of four specimens of hepatic tissue from livers the seat of carcinomatous metastasis shows that the new growth also influences the electrical properties. Thus, in the table immediately preceding, the evidence for retardation exerted by the four specimens of acetone-extracted liver (each of which retarded the leak whether the sign on the leaves was - or +) consisted of 76 individual observations of retardation to 4 of acceleration. In the case of hepatic substance from livers the seat of carcinomatous metastasis, not only did two of the specimens show discordant results affording evidence of acceleration in the electroscope charged with one sign and retardation in the electroscope charged with the other, but the total number of individual observations in favour of retardation was only 52, against 28 in favour of acceleration.

Comparison of the results obtained with the inorganic constituents of bones from non-malignant and those from malignant cases affords confirmatory evidence of the influence of carcinoma upon the electrical properties of the tissues, but here the natural influence of the inorganic constituents appears to be accelerative and in carcinoma the tendency is increased. Thus two out of four samples of inorganic constituents of bone from non-malignant cases afforded discordant results, showing acceleration in the electroscope charged with one sign and retardation in the other, while the total number of individual observations in favour of acceleration was 41 (or 59 per cent.), against 29 for retardation, whereas when derived from cases of carcinoma the discordancy was somewhat less, and the total number of individual observations in favour of acceleration was 53 (or 66 per cent.), against 27 for retardation.

Leaving on one side the evidence afforded by electrical examination of kidney and spleen on the ground that the results are not sufficiently clear to allow of deductions being drawn, I pass to the consideration of substances commonly supposed to be causally related to carcinoma.

In this part of the subject the evidence that I have to offer is of different value in different cases. Electrical examination of clay pipe, of paraffin wax, and of cholesterol gall stone has been carried out on so many occasions that I have more confidence in the case of these substances than in that of others of which the electroscopic examinations are clearly too few. Here, I can only beg your

indulgence and plead the motto of our college as an excuse:

Ὁ Βίος Βραχύς ἢ δε τέχνη μακρῇ.

I have already stated that I find evidence that clay pipes exert an accelerating influence upon electroscopic leak whether the gold leaves be charged — or +. In the case of paraffin and cholesterol gall stone the evidence is no less clear, but both substances exert a retarding influence, and again whether the electrical charge on the leaves be — or +. Experiments with different samples of pitch seem to show on the whole that this substance exerts a retarding influence, but there is no reason to suppose that a uniform effect would be produced by all samples of this or of any other substance of an impure or complex nature. The same criticism holds good in the case of soot, one sample of which yielded me evidence of retardation, while the other gave uncertain results. Metallic arsenic, arsenious oxide, and betel nut appeared to be without effect upon electroscopic leak, but too few experiments were made with them to allow me to speak with confidence.

In my experiments with the substances mentioned above—some of the earliest made in the entire research—I sought to show that the accelerating or retarding property was manifested, even though the substance under examination were covered with an aluminium cap. In numerous instances this appeared to be the case, and undoubtedly, if true, it would afford convincing proof of the similarity of the action of the substances with that of recognized radio-active substances. But owing to the fact that I have found an aluminium disc to become electrically modified by the proximity of a recognized radio-active substance or of a pure cholesterol gall stone, my conclusions on this point require reconsideration. It may be added, however, that even if the influence from the substances did not traverse the aluminium, it would not disprove the possibility of their being essentially "radio-active," since conceivably they might only give off alpha particles, or alpha particles and beta radiations of so low penetrating power that they failed to traverse the aluminium screen.

Having described in brief the electrical effects of the various substances that particularly interest us from a medical point of view, it is now necessary to revert to the recognized radio-active substances.

I have already said that I have reason to believe that recognized radio-active substances induce "antiradio-activity" in an aluminium disc with which they have been placed in proximity, though not in contact, for a certain length of time. This change, I believe, is indicated by the acquisition of a retarding power by the disc on electroscopic leak. But there is no doubt that a metallic surface that has been bombarded by radio-active rays manifests physical change of a gross kind. Thus, the anticathode of an x-ray tube not infrequently becomes perforated in course of time, an aluminium disc which has been exposed to radium for four months shows actual pits on its surface, while an aluminium disc exposed to the relatively feeble radio-activity of uranium for four months shows a loss of polish of its surface over an area corresponding to that which had been in proximity to the uranium. In the last lecture it will be shown that animal cells, in like manner, afford evidence of altered behaviour as the result of proximity to recognized radio-active substances.

This brings us to a consideration of extreme importance. There is no doubt that the facts and the conclusions of the chemist and physicist cannot be applied to biological problems in a crude manner. It is unnecessary to labour this point. It is supported by the whole of chemical physiology and pathology, from so simple an example as the fact that iron in combination with globulin in the form of haemoglobin fails to give the ordinary chemical tests for inorganic iron to the complicated problems of immunity which have shown repeatedly that the animal body is not a mere test tube in which a simple chemical process is taking place. In a word, for the biologist, a necessary preliminary to consideration of radio-activity as understood by the chemist and physicist is a determination whether the radio-active element when in combination with protein behaves in the same way as it does when in combination with other elements to form an "inorganic" compound. It is in the latter form alone that it has been examined by chemist and physicist.

Even if a series of inorganic compounds of a radio-

active element be examined it will be found that the radio-activity as measured by the rate of leak of an electroscope is not identical for all of them. Thus, Colwell and I have shown that the rate of leak of an electroscope in which are examined a number of uranates of the alkalis and alkaline earths as well as the nitrate and sulphates of uranium varies inversely as the atomic weight and the valency of the elements with which the uranium is linked. From this we argued that uranium in combination with the huge protein molecule would show a correspondingly enormous diminution of its influence on electroscopic leak.² This proved to be the case. We showed, further, that the radio-activity of the uranium is not lost, but only masked, for the ash of an incinerated albuminous compound of uranium or of such inorganic compounds as the nitrate and sulphates of uranium or ammonium uranate (which are more or less completely disintegrated on incineration with the formation of an ash consisting chiefly or entirely of an oxide of uranium) produces a profound acceleration of leak. Similar results were obtained with the nitrate and sulphate of thorium and a thorium albuminous compound. Full details will be found in the original paper. Below are given examples in illustration of the statements made above:

Mean values of electroscopic leak in the presence of certain uranium and thorium compounds in the natural state and after incineration.

	Mean Rate of Leak per Hour in Min.	
	Natural State.	Incinerated.
Black uranium oxide	175	177
Ammonium uranate	125	171
Thallium uranate	101	114
Uranyl sulphate	91	177
Uranyl nitrate	80	187
Uranous sulphate	62	159
Uranium Witte-peptone	22.4	126
Uranium serum (pleural fluid)	13.5	85
Uranium egg-white	13	95
Uranium spleen-pulp	10.9	53.6
Thorium sulphate	62	124
Thorium nitrate	55	142
Thorium egg-white	7.5	41.4

Natural leak of empty electroscope 3.6 mm. per hour.

Now the uranium and thorium albuminous compounds contained about 10 per cent. of the radio-active element by weight, and it has already been said that their photographic effect is small and may be completely wanting, even though they be allowed to act on the film through a thin layer of air, while at least the thorium compound fails to affect the film through a screen so thin as that formed by brushing egg-white over tissue paper. Evidence of radio-activity in the physical sense is therefore reduced to a very low point, and it is easily conceivable that with smaller percentages of the radio-active element, or in combination with still larger molecules or combinations of molecules, all evidence of "radio-activity" should be lost, although the fact that the substance in question contains the recognized radio-active element would be immediately demonstrable on removing the impeding constituents of the compound by incineration.

Proceeding on these lines I have incinerated animal substances of all kinds, in the hopes of setting free a radio-active substance that would be recognized by physicists and chemists, but without success. Clearly the tissues contain no radio-active substance which can survive exposure to a white heat. Whether they contain a radio-active substance that can withstand a temperature of 300°, after which skotographic action disappears, but is dissipated or disintegrated between 300° C. and the temperature of white heat, it is impossible to say. In any case experiments with albuminous compounds of recognized radio-

active substances, such as uranium and thorium, indicate that small evidence of radio-activity manifested by an animal tissue does not necessarily mean that that tissue contains only a small amount of a radio-active element. The smallness of the evidence may simply depend upon the relative completeness with which the radio-activity is masked by the albuminous molecules with which the radio-active element is in combination.

By comparing the rates of electroscopic leak when the substance is directly exposed to the charged leaves, and when it is separated from them by a screen of thin aluminium foil, it is possible to separate that portion of the leak which is due to the impact of alpha particles from that portion due to beta and gamma rays. As is shown by the following table, the masked radio-activity consists chiefly, if not entirely, of alpha particles. In the case of thorium compounds, the table is of particular importance, inasmuch as it not only shows the great increase of leak due to alpha particles after incineration, but also an enormous disappearance of some radio-active element producing beta and gamma rays during incineration. It is necessary to add that the amount of radio-activity that is removed from thorium compounds by incineration varies considerably under a number of circumstances that need not be mentioned here, but that all the thorium compounds given in the table were prepared from a single sample of thorium, and are comparable amongst themselves, though not with those given in the preceding table.

Portions of the rate of leak per hour occasioned by certain uranium and thorium compounds due to alpha particles and to beta + gamma radiations.

	Natural State.		Incinerated.	
	α Particles.	$\beta + \gamma$ Rays.	α Particles.	$\beta + \gamma$ Rays.
Black uranium oxide	145.8	29.2	144.0	33.0
Ammonium uranate	101.2	23.8	145.5	25.5
Thallium uranate...	79.4	21.6	82.6	21.4
Uranyl sulphate ...	57.0	35.0	142.8	37.2
Uranyl nitrate ...	52.4	27.6	151.9	35.1
Uranous sulphate ...	52.8	11.2	127.0	11.0
Uranium egg-white	4.8*	0.6*	124.0	1.8*
Thorium sulphate...	24.1	77.9	78.4	27.6
Thorium nitrate ...	21.7	70.6	127.8	16.2
Thorium hydroxide	104.0	496.0	123.0	22.0
Thorium egg-white	3.1*	1.4*	46.5	7.8*

* In the case of these low values the ascertained leak has been corrected by the natural leak of the electroscope determined specifically for the purpose on each occasion; elsewhere it is neglected.

As to the work done and the changes produced within the molecule by the imprisoned alpha particles, it is only possible, as yet, to speculate. Evidence has been given that carcinoma material, with its tendency to accelerate electroscopic leak, modifies the electrical conditions of the tissue in which it lies; it is not impossible that the bombardment with alpha particles undergone by an aluminium disc in proximity with a recognized radio-active substance may lead to that "antiradio-activity" of the disc which I have described.

LECTURE IV.

INFLUENCE OF RECOGNIZED RADIO-ACTIVITY AND OF CERTAIN SKOTOGRAPHIC NON-MALIGNANT MATERIALS UPON THE DIVISION OF ANIMAL CELLS.

HITHERTO the experiments I have described have been of a chemical or a physical nature; the next step, and the last I am at the present time in a position to make, will be into the animal kingdom. Whatever the results we may have obtained, their sole importance to us as biologists, and even more as medical men, lies in any application they may have to the processes going on in the animal cell. If radio-activity, if the peculiar skotographic and electrical properties we have now found to be associated with a number of substances some of which are

derived from the animal body, influence cell nutrition, cell growth, cell multiplication, they are of interest to us; if not, we may leave them on one side.

The cell which I have chosen for this part of the research is the ovum of *Ascaris megalocephala*, an intestinal entozoon of the horse. When removed from the oviduct the ovum shows a thick cell membrane, a single undivided cell, and a general absence of pigment or foodstuffs. Since it is obtainable in enormous numbers, is clearly visible with a half-inch objective, and passes through the changes up to the formation of a complete living and moving embryo worm within a few days or a few weeks, according to the temperature at which development is allowed to proceed, it is very suitable to our purpose.

Examination of the development of the ovum when it has been exposed to the influence of recognized radio-activity, has been carried out in the case of x rays, radium, thorium, and uranium.² The results agree remarkably, not only in their general direction, but also in the fact that certain special effects are produced by the two most potent members of the group—radium and x rays.

The experiments consisted in determining the rates of division of the cells under conditions that differed only in respect of their exposure or non-exposure to radio-activity. In the case of x rays, exposure lasted varying times, from two minutes to twenty minutes, and the ova were exposed to the rays at the commencement of the experiment when they were all in the one-cell stage. In the case of radium, thorium, and uranium the ova were exposed to the action of the substance during the whole time of their development. Inasmuch as x rays are gamma rays alone, while radium, thorium, and uranium give off alpha particles as well as beta and gamma rays, the experiments differed in this respect. Moreover, since the radium, thorium, and uranium were exposed to the ova without any intervening substance except a thin layer of air, the cells were acted on by all three constituents of radio-activity in the case of these substances.

Below are given the results of an experiment using x rays.

Characters of Cell Division in 200 Ova after Exposure to X Rays for Varying Periods.

Immediately after exposure:
All cells in 1-cell stage.

24 hours after exposure (room temperature):

	1-cell stage.	2-cell stage.
Control ...	158	43
2 min. exposure ...	140	60
4 " " " " " " " "	151	49
6 " " " " " " " "	164	36
9 " " " " " " " "	175	25
12 " " " " " " " "	184	16
15 " " " " " " " "	187	13
20 " " " " " " " "	194	6

48 hours after exposure (room temperature):

	1-cell stage.	2-cell stage.	3-cell stage.	4-cell stage.
Control ...	74	65	26	35
2 min. exposure ...	71	52	22	55
4 " " " " " " " "	81	42	21	56
6 " " " " " " " "	90	46	20	44
9 " " " " " " " "	107	53	21	19
12 " " " " " " " "	123	43	14	15
15 " " " " " " " "	104	60	15	21
20 " " " " " " " "	126	57	13	14

This experiment, which has been repeated on many occasions with similar results, shows conclusively that x rays have a dual effect. Short exposures accelerate, long exposures retard, cell division.

Since the ovum does not increase in size during development it becomes impossible to conduct the experiment satisfactorily during the period between the four-cell stage and the early embryo, but with the formation of the embryo the accelerating and the retarding influences of the x rays again become manifest. Thus the ova, concerning which details have been given above, were transferred to the incubator at 37° C. during the third and fourth days after exposure to x rays, and it was then found that the control specimens showed immature embryos and 1 living and moving worm; the two-minute and four-minute specimens were indistinguishable from the control, and also showed 1 living and moving worm apiece.

the greater part of the time at my disposal in this way, partly because in cancer research there is at present more need for practical experiment than for theoretical disquisition, and partly because the Croonian Lectures afford a rare opportunity for presenting the results of a prolonged research in an orderly manner. It is right, however, that in the time remaining to me I should summarize my results, and, as far as may be, consider established facts in connexion with carcinoma under the light that they afford.

The original question with which I started—namely, Do the physical agents which are commonly supposed to give rise to cancer (clay pipes, soot, etc.), and do samples of carcinomatous material afford evidence of the possession of radio-active properties?—is not conclusively answered. In certain respects they behave like the radio-active materials of the chemist or physicist, but in no single instance do they respond to all the criteria of recognized radio-activity. Thus, I have shown that many of the substances affect a photographic plate in the dark; but, on the other hand, few can act on the plate if a screen be interposed, and even in those instances in which a positive result is obtained under these circumstances, it is doubtful whether the interposed celloidin screen is fairly so called. Nevertheless, it is doubtful whether the power of acting through a screen is a necessary criterion of radio-activity, since I have shown that albuminous compounds of recognized radio-active substances may possess a power of acting on the photographic plate which will not traverse an extremely thin screen, and, indeed, may be devoid of photographic powers altogether. In the latter respect they are comparable with clay pipe, inasmuch as neither type of substance acts on a photographic plate and both accelerate the discharge of an electroscope. In the same category comes carcinoma material which has been extracted with acetone or with water and subsequently with ether. Possibly, too, some specimens of spleen and of the inorganic constituents of bone are to be reckoned in the same class.

Even a greater difficulty arises in connexion with those substances which I have found to retard electroscopic leak. Such a property is entirely repugnant to present ideas of radio-activity. If I am correct in asserting that evidence of retardation can be obtained by the use of recognized radio-active substances, as in the case of aluminium discs which have been placed in proximity to uranium, thorium, or pitchblende, this difficulty is overcome. It may be that the dual accelerative and retarding influence which I have found all forms of radio-activity to exert upon the development of the ova of *Ascaris megalocephala* will help in determining this important question. Already this line of research is indicating that certain animal extracts having skotographic powers resembling those of radio-active substances up to a certain point are able to influence the rate of development of animal cells when acting on them from a distance, and through the screen of their own egg case. It is not impossible that we shall find that the laws of radio-activity as determined by the physicist require some modification when adopted into biology owing to the presence of the protein molecule, just as the laws of filtration and osmosis have required adjusting to the special circumstances of the case. I showed some years ago that the presence of even a minute trace of protein profoundly modifies the rate of osmosis,¹ and I showed in the last lecture that combination of a radio-active element with a protein molecule profoundly modifies the rate with which it induces electroscopic leak, and its photographic powers.

Table showing Principal Skotographic and Electroscopic Results hitherto Obtained.

Type of properties:	The substance acts on a photographic plate directly and also through a screen. It <i>accelerates</i> electroscopic leak whether the charge on the gold leaves be — or +.
Recognized radio-active substances	Radium, uranium, thorium, uranium aluminate some weeks after its preparation.
Other substances of research	No member found.

Type of properties:	The substance acts on a photographic plate directly but <i>not</i> through a screen. It <i>accelerates</i> electroscopic leak whether the charge on the gold leaves be + or —.
Recognized radio-active substances	Uranium aluminate directly after its preparation, thorium aluminate weeks after its preparation, doubtfully, directly after preparation.
Other substances of research	Carcinoma material after extraction with either water or ether but not both.
Type of properties:	The substance acts on a photographic plate directly and also through a screen. It <i>retards</i> electroscopic leak whether the charge on the gold leaves be + or —.
Recognized radio-active substances	No member of the group found.
Other substances of research	Solid mass of hepatic material.
Type of properties:	The substance acts on a photographic plate directly but <i>not</i> through a screen. It <i>retards</i> electroscopic leak, whether the charge on the gold leaves be + or —.
Recognized radio-active substances	No member of the group found.
Other substances of research	Carcinoma extract, watery or ethereal, non-malignant liver, before and after extraction with acetone, acetone extract of liver, cholesterol gall stone.
Type of properties:	The substance has <i>no</i> photographic action whatever. It <i>accelerates</i> electroscopic leak whether the charge on the leaves be + or —.
Recognized radio-active substances	Thorium (?) and certain specimens of uranium aluminates directly after preparation.
Other substances of research	Carcinoma material after extraction with acetone, clay pipe, possibly some others.
Type of properties:	The substance has <i>no</i> photographic action whatever. It <i>retards</i> electroscopic leak, whether the charge on the leaves be + or —.
Substances prepared by means of recognized radio-active substance	Aluminium discs after proximity to uranium or thorium or pitchblende.
Other substances of research	Aluminium disc after proximity to cholesterol gall stone, paraffin wax, liver substance after extraction with acetone.

The Relation of Radio-activity to Carcinoma.

Leaving now the question whether the substances commonly supposed to be causally related to cancer and certain animal tissues, including carcinomatous material, are radio-active as unanswered—and, in our present state of knowledge, as unanswerable—we may pass to consider recognized facts in connexion with carcinoma as a disease in the light of the experimental evidence I have adduced. It is impossible for me to traverse the whole field, partly from lack of time, partly because I should thereby introduce too much contentious matter. I shall therefore confine myself to a few salient points, offering you something in the nature of an impressionist picture.

One of the most certain features of carcinoma (at all events, as we meet with it in this country) is that it occurs more commonly in women than in men, and that the case-incidence, corrected by the number of persons of the sex living at various ages, in both sexes runs on parallel ascending lines up to the age of about 55 years, while after that age the lines diverge, liability to the disease continuing to increase in males but undergoing a sharp diminution in females. It is certainly remarkable that the degree of skotographic power of the liver in the two sexes and at different age-periods affords a pair of curves agreeing absolutely in these points with the curves of cancer liability (Fig. 15). It is possible that the identity of the two pairs of curves is a coincidence, and that both cancerous and skotographic conditions may depend upon some common underlying cause—for example, senility. Thus, curves made for the incidence of fibrotic kidney and greyness of hair would probably run parallel courses, but no one would infer that the one bears a causal relation to the other. But when one finds that the liability of liver, kidney, lung, and spleen to primary, and in the main to secondary, growth varies directly with their skotographic power, that the liability of gall bladder, urinary bladder, and kidney to carcinoma varies directly with the skotographic value of the calculi by which severally they are affected, that carcinomatous

material possesses this skotographic power, practically without exception, and that the normal skotographic power of a tissue is modified by the presence in it of a carcinomatous mass, the idea that the two are in some way interdependent is strengthened. And when one further finds that these tissues, or their extracts, are capable of influencing the rate of division of animal cells, the suggestion that in them lies the key of a disease which is, after all, nothing more than a disorderly overgrowth of a particular variety of cell, becomes alluring. Nor is the fact that certain of the extracts have been found to possess accelerative, while others possess retarding, powers on development a difficulty, for it is clear that for the occurrence of a carcinoma it is as necessary for the subjacent tissues to undergo a diminution of their normal resisting powers to the encroachment of the epithelial cells as for these latter to undergo an increase in their normal rate of reproduction.

This brings us to the question of metastases. I have long felt that the metastases in carcinoma are not regarded in their proper light. Stripped of non-essentials, the occurrence of a metastasis simply means that a cell which is capable of growth is lodged in a situation at which it is not killed. That is to say, the tissues into which a carcinomatous cell is carried by embolism, tissue permeation or other means plays as considerable a part in determining the occurrence or non-occurrence

Nevertheless, the fact that the existence of carcinoma in a body affects the skotographic power of the liver of the patient, even though the liver itself be devoid of metastasis, indicates that an influence is exerted by the carcinoma, or the initial cause of the carcinoma, upon distant parts. And in this connexion one may ask whether it is not possible that those rare cases may be thus explained in which

death in carcinoma cannot be attributed with fairness either to the mass of growth, septic absorption, mechanical interference with vital parts, or other similar cause. One of the most noteworthy points in connexion with carcinoma is that a mass will kill, being carcinoma, which would probably not kill if (*caeteris paribus*) it were inflammatory. It is only necessary to compare the certain death from so small a mass of disease as is often a carcinoma of the body of the uterus, with the relatively good prognosis of a far more extensive tuberculosis, actinomycosis, or tertiary syphilitic condition.

If the general liability to carcinoma in males and females be split up into its component parts and the liability to carcinoma at different sites be considered individually, certain interesting points are disclosed. This has been done for 6,421 cases of cancer at the Middlesex Hospital of which details as to age are available. The cases are distributed as follows: Uterus, 2,205 cases; breast, 2,126 cases; alimentary tract from stomach to rectum, 470 female and 586 male cases; tongue and rest of mouth, 783 cases (male); lip, 251 cases (male). The total

number of cases of each kind in each quinquennial age-period has been corrected for the number of persons (male or female, as the case may be) surviving at that age-period from 100,000 persons born. The curves thus formed are given in Fig. 16.

The most striking point in the curves is that whereas all of them show a rising liability with increasing age, this increasing liability only persists to the end of life in the case of cancer of the lip. In every other instance a maximum is reached, after which the liability to cancer diminishes with more or less suddenness. And, further, the maximum liability to cancer of a special organ does not occur at the same age as

the maximum liability to cancer of another organ, nor are the ascents and descents of the different curves equally rapid or high in all cases.

There is thus a great contrast between cancer of the lip and cancer of the uterus, for example, so far as the liability of individuals to the two types of disease is concerned. This difference may clearly depend upon either a difference in the incidence of the cause of cancer or

Fig. 15.—PL, Female liver skotographic value; ML, male liver skotographic value; LC, female liability to cancer; MC, male liability to cancer.

Fig. 16.—Liability to carcinoma at different age periods. (Middlesex Hospital.)

of them they are destroyed at the seat of their lodgement.

In the difference between a tissue which allows a transported carcinoma cell to grow and multiply and a tissue which destroys it consists it is impossible to say, but the different properties of tissue extracts upon the division of the ova of *Ascaris megalocephala* are such that in them may perhaps lie the solution of the question.

upon a difference in the tissue upon which the cause is acting. So far as a difference in the tissue is concerned, there is no doubt that the maximal liability to cancer of the uterus occurs about the menopause, and that it diminishes with great rapidity immediately after. But the uterine, and particularly the cervical, changes following the menopause are amongst the least marked of climacteric changes, and in any case are minute compared with the uterine modification following a pregnancy. If, however, we consider the question from the point of view of a difference in the incidence of the exciting cause of the disease the matter becomes simpler.

The cervix uteri is particularly suitable for an inquiry into the etiology of carcinoma. It is a limited region, it is in the majority of cases affected by the simplest form of carcinoma, the squamous cell variety, it is placed out of reach of an infinitude of accidents and forces which act upon other parts covered with squamous epithelium, and it is liable to three conditions, two of which, namely, bathing with menstrual blood and bathing with seminal fluid, are peculiar to it, while the third—laceration during childbirth—is merely a trauma more or less resembling traumata in other regions, and, once occasioned, persists throughout life. At the same time, as it is more than usually protected from outside influences, it is one of the commonest, if not actually the commonest seat of carcinoma. Of these three conditions, the two that are peculiar to the cervix are those which attract most attention when considered in relation to the age for the maximum liability to carcinoma of the cervix, partly because traumata occur in other regions, partly because a period of many years usually elapses between the last parturition and the age of maximum liability; and, considering menstrual blood and seminal fluid as possibly containing the essential cause of carcinoma of the cervix, menstrual blood must be put on one side, if only for the reason that if it were the cause one would expect that vagina and vulva and body of the uterus would not show so marked an inferiority in liability to carcinoma as they undoubtedly do. This leaves the seminal fluid; and it is a remarkable fact in this connexion that the spermatozoon is the most potent instigator of cell division known when it acts upon a specific cell, the ovum, and that an extract of the testis of the herring (which consists almost entirely of spermatozoa) favours the division of the cells of the ova of *Ascaris megalocephala* to an extraordinary extent, and at the same time possesses marked skotographic powers (Fig. 17).*

In the case of the breast it appears to me that the observation of MacCormac that various bacteria possess skotographic powers is of great importance in conjunction with the fact that a greater or less degree of chronic mastitis is so commonly met with in mammary carcinoma. From this point of view, mammary carcinoma may be brought into line with carcinomata arising on old cicatrices and long-standing ulcers, whether these be simple or lupoid. It is, indeed, remarkable that the only varieties of bacteria which have been found to possess marked skotographic powers are those which pre-eminently affect man, the pyogenic staphylococci, *B. tuberculosis*, *B. diphtheriae*, while man amongst the animal kingdom is so much more commonly affected by carcinoma that it may be termed a pre-eminently human disease. When it is remembered that bacteria—especially pyogenic and tuberculous bacteria—may remain latent for years, when it is remembered that the skotographic action, if not of bacteria, at least of other animal substances, may persist for a period, certainly of months and probably of years, the question arises whether we shall not find the essential cause of carcinoma affecting mamma, cicatrices, old ulcers, directly connected with the bacteria underlying the primary chronic inflammatory condition. If this be so, if the bacteria introduced into the breast, possibly during some lactation period, carry with them by virtue of their skotographic power the cause of a carcinoma which develops years later, we should expect the feebly skotographic bacteria to induce carcinoma later in the individual's life than the far more powerful spermatozoa; we should expect the period of maximal liability to a carcinoma of bacterial origin to be spread over a larger range of

years than one of spermatozoal origin, we should expect a later onset of diminution in liability with a carcinoma of bacterial origin than with one of spermatozoal origin, but in both cases we should expect the liability to cancer to diminish in later life. In a word we should expect to find carcinoma of the breast and carcinoma of the cervix showing just those differences of incidence which they actually manifest.

But if, in the case of the uterus, it is difficult to associate the occurrence of carcinoma with peculiarities on the part of the tissue itself, this is even more difficult in the case of carcinoma affecting that part of the alimentary tract lying between stomach and rectum. A glance at the curves of liability to cancer in these regions drawn up for males and for females shows that in males the liability is not only greater but also that it reaches a maximum some ten years earlier than in females, and persists at that maximum for five years longer. We cannot consider that there is so striking a difference between male and female alimentary tissues as this would indicate in the absence of definite evidence on the point. It is easier to imagine that some factor leading to increased division of epithelial cells is more potent in males than in females during the age-period 50 to 69. It would serve no good purpose to discuss here what that factor may be, but it may be pointed out (a) that Sir J. J. Thomson has shown that certain foodstuffs—namely wheat flour—may be radio-active; (b) I have shown above that many animal substances have properties which may be radio-active, that both definitely recognized radio-active substances, and extracts of animal tissues are able to accelerate cell division in the ova of *Ascaris*; and (c) that, partly as a result of the greater degree to which they are occupied in arduous labour, men consume more food than women.

I have left consideration of the curves obtained for carcinoma of the lip, and of the tongue and other parts of the mouth, to the last because of their great dissimilarity in spite of the similarity of the tissues concerned, and of the identity of most of the conditions to which those tissues are subjected. This dissimilarity of the curves of liability to carcinoma, and particularly the fact that the liability to carcinoma of the lip undergoes no diminution in old age such as is observed in the case of carcinoma in all other sites that we have examined, is strong evidence that some fundamentally different condition obtains in the two situations. The persistency with which the old man clings to his pipe, holding it between his lips, whether actually smoking or not, whether awake or dozing as he sits in the sun or by the fire-side, is as characteristic of the ages above 70 as is the toothless condition which commences to set in about 65. On the assumption that the pipe in some way is directly related to carcinoma of the lip, while the teeth are in some way directly related to carcinoma of the tongue and other parts of the mouth, the curves of liability to this disease in the two situations should be exactly as we find them to be.

It may be urged that the observations I have brought forward are nothing more than evidences of that "chronic irritation" which since the time of Virchow has been held to play an important part in the causation of carcinoma. To this my answer must be that the term "chronic irritation" is meaningless, and only indicates that some common factor exists in a variety of conditions that differ otherwise to the greatest extent. Is it not possible that the common factor, which must be capable of stimulating the growth of certain cells while it depresses the growth of others, which must reside in substances of the widest diversity, which must act with varying intensities in different cases though always with comparative slowness, the natural action of which must be progressive so long as it persists, should be radio-activity? The α rays cause carcinoma, they stimulate (like other radio-active substances) the growth of cells, and, again, they retard the growth of cells, carcinomatous material, non-carcinomatous material, extracts of animal tissue, various substances usually regarded as causally related to carcinoma, possess properties resembling those of recognized radio-active substances to a greater or less degree when considered from the physicist's point of view, and there is evidence that they possess powers of stimulating or depressing the division of animal cells. Such similarities are at least suggestive.

*The freedom of lower animals from carcinoma cervicis, I suggest, is explained by their entirely different sexual habits. Its occurrence in an undoubted virgin would be explicable on the lines sketched in the next paragraph.

At the same time as radio-activity—using that term to cover the properties of other than recognized radio-active substances for the moment—would serve to explain a large number of the salient features of carcinoma as a disease, it would fall in line with other facts that have been made known more recently, and often affords a common ground for views that appear at first sight to be diametrically opposed.

It would fall in line with the observations of Farmer Walker, and Moore on the frequent occurrence of heterotypical and irregular mitoses in malignant new growths, for all observations go to show that the ova of *Ascaris megalocephala* divide with great irregularity when they are exposed to recognized radio-activity, and the same is true when they are exposed to the influence of any of the watery extracts of animal substances that have been mentioned above. It would fall in line with the observations that there is a deficient secretion of pepsin and trypsin in carcinoma, for Colwell and others have shown that the activity of these enzymes is largely diminished when they are exposed to radio-active influence.⁹ It would fall in line with the observation that the erptic power of the tissues in carcinoma cases is not diminished more than in other chronic diseases accompanied by wasting (Colwell¹⁰), for exposure to radio-activity does not affect the erptic power of a tissue extract in the slightest degree. It would fall in line with the fact that certain varieties of carcinoma, notably those which are superficial, are curable by radio-activity; for, as is shown by the cases of diphtheria, typhoid, tetanus, anthrax, rabies, and other microbic diseases, the agent producing the disease is prepotent in elaborating the remedy. It would fall in line with the fact that carcinoma is primarily a disease in which a definite variety of cell—the epithelial—is concerned, for there is evidence that radio-activity has selective powers—for example, in its action upon the specific cells of the testicle and upon the spleen. It would fall into line with the remarkable observations of Ehrlich and Apolant, and of Haaland, that in mice transplantation of one type of tumour may lead, as they believe, to the origination of another type from the tissues of the host, for the cells of a carcinomatous mass are endowed with properties resembling those of recognized radio-active substances in many respects.

On the other hand, it would not be opposed to a belief in "cancer houses and localities," for there is no reason why the soils of districts or the materials of which houses are built should not differ in the degree to which they are radio-active, nor why the local radio-activity should not be in certain instances so considerable that cancer arises in successive inhabitants time after time. In a sense the electrical department of every hospital is a "cancer house." It would not be opposed either to an infective or non-infective, a contagious or non-contagious, an animal or vegetable parasitic, a parasitic or non-parasitic, an hereditary or non-hereditary view of cancer, for it would only be concerned with the question whether the inculcated agent is radio-active or not. So far as certain bacteria possessed the properties we are considering, the carcinoma associated with them might be regarded as bacterial and infective, but the bacterial and infective properties would be accidental and non-essential. So far as the agent which leads to hereditary transmission was provided with "radio-active" properties cancer would be hereditary, but the inheritance of cancer would be accidental and non-essential. Similarly it would be opposed to Cohnheim's theory of embryonic rests, to Virchow's theory of mechanical irritation, to von Hausmann's theory of anaplasia, to Ribbert's theory of tissue tension, to Adam's theory of habit of growth—for it would constitute the underlying force required by each.

There remains the question whether by applying radio-activity we are able to produce carcinoma. To this question I can only reply that numerous experiments have hitherto resulted in failure. I have exposed rats and mice to the action of x rays or to uranium or thorium for months; I have kept a glass tube containing radium in the abdominal cavity of a rabbit for months; I have exposed the ears of rabbits to x rays for prolonged periods and under different circumstances; but, so far, the only cases of carcinoma resulting from exposure to radio-activity are those which have occurred in the human sub-

ject. Yet the experiments I have mentioned have not been without importance, for, as Rowntree¹¹ has shown, the changes in the rat's tail, and even more those in the rabbit's ear, resemble those in human x-ray dermatitis, while there is in certain places a well-marked overgrowth of epithelial cells. In the case of the rabbit's ear, indeed, he finds that the epithelium on the under, or indirectly exposed, surface shows an irregular arrangement of the hypertrophied epithelial cells which appears to be on the border-line between non-malignancy and malignancy. When we can determine that that border-line shall be crossed, one of the greatest steps towards a discovery of the cure for carcinoma will have been made.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

TREATMENT OF VOLVULUS.

THE article by Mr. Waterhouse on volvulus, in the JOURNAL of May 29th, is most valuable, as pointing out that the site is usually the sigmoid flexure, and so almost always remediable by enema in the early stage. I believe his advice would have been more useful to the general practitioner, who treats most of these cases, if he had descended to particulars as to how an enema should be given. It may be that the hint I am about to give is found in various textbooks and periodicals, but in thirty years' reading I have never met with it, and only found it out by painful experience. One case, as a sample, will illustrate my meaning. A farmer, aged 63, fell from a load of hay on to the meadow and got concussion of spine followed by partial paralysis of the lower limbs; a catheter had to be passed for two weeks. During the following three years he suffered from constipation, and at the end of this time I was sent for urgently—a distance of eight miles—to see him. I found him with bowel obstruction; the abdomen was tympanitic and as tight as a drum; breathing was shallow, owing to pressure on the diaphragm, but there was no vomiting nor eructations. I gave enemata in the ordinary way, and after nearly an hour I only removed some small scybala from the lower bowel. It was evident that the obstruction was higher up. I left the patient no better, gave some calomel and opium, and promised to return early in the morning. This I did, taking with me a long tube of soft rubber similar to that used for passing into the stomach. Attaching this to the bone pipe of a Higginson syringe, I gave an enema. The tube when passed through the sphincter is very apt to curl up in the wide or ballooned part of the rectum, and considerable difficulty is often experienced in getting it to enter the upper narrow part, which owing to the curve of the sacrum goes forward at an angle. I pushed the tube as far as it would go, and then, pumping in water under pressure, the bowel dilated in front and I was able to gain an inch or two at a time. Continuing this manoeuvre, the whole 32 in. of the tube were at last passed inside the sphincter. I felt the pumping tension relax, heard a gurgling, but continued pumping for a little longer. I now detached the bone pipe from the tube and allowed the water to come away, when the whole gas followed, the abdomen relaxed, and the patient was well.

I have on different occasions had to supplement the tube by a second, and I advise that the tube be 3 ft. or over. I am persuaded this hint of mine may be of service to some sorely perplexed general practitioners.

ROBERT MOWBRAY, M.D.

Reports of Societies.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Friday, June 18th, 1909.

Sir PATRICK MANSON, K.C.M.G., in the Chair.

The Future of Tropical Medicine.

PROFESSOR RONALD ROSS, as newly-elected President, delivered an address dealing with the future of tropical medicine. The subject, he said, was a wide one, and required comprehensive and philosophic treatment. He would, in the first place, emphasize the desirability of a careful study of the national history and decadence of the kingdoms and empires of the Old World, and the effects which had been exercised on the prosperity or decay of nations by endemic disease. The work of Mr. W. H. Jones and Drs. Ellett and Withington on the influence of malaria on Greek history was known to them all; and it was only a summary of what had occurred in every part of the world. The physical deterioration which was now so prevalent in large tropical cities he believed was due almost entirely to helminthiasis; and there was no reason why the tropics should not produce healthy and vigorous men in the same way that they produced the strongest and finest specimens of life in the animal kingdom. The scientific history of tropical medicine had also to be carefully studied, and he thought that the publication of monographs on special subjects, and of reprints of classical papers, should receive greater attention. He had long insisted that, in the ordinary medical curriculum, parasitology and perhaps medical entomology should be taught. Diplomas issued by qualifying bodies in Great Britain certified that their holders were qualified to practise anywhere, but that claim could scarcely be justified at present. The future of tropical medicine lay to a great extent in the domain of therapeutics, and fuller research in this direction was urgently demanded. In the tropics, as at home, the housing of the poor was another burning question. It had been shown by one or two of the most advanced nations in Europe that it was possible to have cities without slums, and he was hopeful that the future would banish from their eyes the miserable sights which they now saw everywhere in the tropics. Investigation of possible improvements in the present methods of the disposal of sewage and town refuse was also urgently required; and other measures, such as the provision of wholesome water supplies, the management of wells, and the extinction of vermin in the tropics, were pressing and vital necessities. To achieve these objects sanitary organization must be completely remodelled. The present deplorable condition of things was not surprising; it was only fifty years ago that sanitation on scientific lines had been undertaken at home; and in a sense great improvements had already been made in the tropics. But further advances were most urgently demanded, and it was essential that the sanitary services of practically the whole of our tropical colonies and possessions should be thoroughly organized. At the present moment the health departments resembled the units of an army which had no general; and looking at the question merely from the monetary point of view, judicious expenditure on reorganization would pay. Let them not fall into the mistake that discovery, great or small, finished their duty; research was not a mere academical amusement consisting in the publication of elegant articles adorned with coloured plates. They had not only to teach, but to beseech, demand, and command. They were apt to take too haughty a view of their scientific work, to stand above and apart from the throng of men for whom they were working. It was for them to descend, to go personally into the battle, and fight hand to hand in order to save their fellow men from grave and imminent dangers. Sir PATRICK MANSON said that it was true they had not yet got the general public to believe the truths which had been shown to them. The fault was, perhaps, not altogether on one side, and medical men had, he thought, failed to convince, largely from lack of articulate expression and eloquence. Governments had often been blamed for their

deliberation in adopting new and extensive measures of sanitation, but it must not be forgotten that circumspection had been forced on them by the mistakes of sanitary advisers. In India, for instance, millions of public money had been wasted on the supposition that cholera was an airborne disease, and if authorities now believed that the most ambitious schemes did not always mean the most rapid progress, they had abundant precedent to justify them.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DISEASES OF CHILDREN.

Friday, May 28th, 1909.

Mr. R. CLEMENT LUCAS in the Chair.

Tetany and Dilatation of the Colon.

DR. F. LANGMEAD showed a case of facial irritability of fifteen months' duration succeeding tetany in association with dilatation of the large intestine. The patient, a girl, aged 8, was admitted to hospital for tetany in April, 1908. Her facial irritability was pronounced on both sides. No signs of organic nervous disease were found. The colon was dilated. Attacks of laryngismus stridulus occurred. The urine contained indican. The colon was daily washed out, whilst castor oil and salol were given by the mouth. Sauerin, koumiss, and thyroid were also used without effect. The washing out was then discontinued, and energetic treatment with bismuth and opium applied. Enemata and massage were then used for a week with improvement, and after two months she had gained 4 lb. in weight and the tetany and laryngismus had subsided. The massage was continued for three months. The signs of dilatation of the colon then disappeared, but the facial irritability had persisted. A month ago she had another attack of tetany with vomiting. The author also mentioned nine other cases exhibiting relapsing tetany, dilated large intestine, and unhealthy offensive motions, occurring at an age beyond that of the usual infantile tetany. All had died except the patient exhibited. On tapping the cheek of the child an immediate rapid contraction of the muscles on the same side of the face was elicited.

Oxycephaly.

MR. SYDNEY STEPHENSON showed a case of oxycephaly in a boy aged 32 days, admitted to hospital with ulceration of the right cornea. The right eyeball protruded from between the eyelids immediately after birth. Labour was easy. The eye bulged forth whenever the baby screamed or was bathed. The child weighed 5 lb., had a red and wrinkled skin, loud "snuffles," and a slight papular rash on the hands and arms and trunk. The skull was typical of oxycephaly, the frontal region rising steeply and overhanging the face. The cranium was deficient as regards total size and capacity. All the bones and sutures appeared to be present. The eyeballs, especially the right one, were prominent, though they could still be covered with the eyelids. The orbits were clearly deficient in depth. The CHAIRMAN said that those interested in such cases as this might like to know that at the Royal College of Surgeons all the abnormal skulls had been arranged in series by the new Curator, Dr. Keith.

Congenital Dislocation of the Hip.

MR. RALPH THOMPSON read a paper upon congenital dislocation of the hip-joint, and showed a number of specimens in illustration of the points arising. He put forward the view that the changes associated with pressure or static dislocation of the hip were too frequently regarded as primary and as producing the dislocation, whereas in many cases of congenital dislocation no deformity was noticed until the child began to walk, and the deformity occurred in well-developed female children, in whom the mechanical conditions were more likely to produce dislocation at the time of the adoption of an erect attitude than was the case in males. The changes found were a shallow and triangular acetabulum, a small flattened head of the femur with a short and anteverted neck, deficiency in the iliac segment of the acetabulum and hour-glass constriction of capsule, a stretched or absent ligamentum teres and some coxa valga and shortening of the leg below the knee. These conditions could all be explained by considering the mechanics of

the joint in children of 2 to 3 years of age. Mr. HUGH LETT said the theory brought forward was very interesting and important. All who had seen cases of congenital dislocation of the hip must have been struck with the remarkable fact that those children did not appear to have anything wrong until they were 3 or 4 years of age. No accident or anything of the kind had been noticed; simply that the child had perhaps limped ever since she could walk. He would like to consider the paper more carefully before speaking very decidedly about it; but there was very much, from an anatomical point of view, in what had been brought out, particularly in connexion with the fetal pelvis, and the relations of various lines of force in male and female. He believed Mr. Thompson's view would very likely be accepted by very many authorities; and, even if they did not accept it, they were bound to weigh it with very great care before putting it on one side. The CHAIRMAN said he had been accustomed to point out that when a child was not allowed to walk on one of its limbs from any cause, it was not only the thigh which was shortened, but measurements showed that the foot and all the bones of the limb were shortened as a result of the lack of use. He understood from the argument that, as the female was less protected than the male from dislocation of the hip, it was unwise to place the female child on her feet so early as the male child.

Medical Inspection of School Children.

In the course of the evening the following resolution, passed by a committee which was appointed some time ago to consider the matter, was discussed and adopted:

It is desirable that the Board of Education should issue forthwith a complete set of forms for use in the medical inspection of elementary school children, in accordance with Circular No. 582 issued by the Board on January 23rd, 1908, and should issue definite instructions to medical officers as to the manner in which the medical inspection shall be carried out.

Rebelsus.

THE URANIAN.

The Urning and the Carpenter
Were sitting hand in hand;
They wept because Homogeny
Is generally banned;
"If prejudice were swept away,"
They said, "it would be grand!"
"If to abnormal practices
We publicly adhere,
Do you suppose," the Urning sighed,
"The Law might interfere?"
"I dread it," cried the Carpenter,
And shed a sterile tear.

MR. EDWARD CARPENTER is responsible for a slim gilt-edged volume, published at 3s. 6d. net, with all rights reserved, entitled *The Intermediate Sex; a Study of Some Transitional Types of Men and Women*.¹ It is a collection of five articles of his own, plus an appendix, "which the author hopes will prove helpful, though he does not necessarily endorse all the opinions presented." These articles reiterate *ad nauseam* praise and laudation for creatures and customs which are generally regarded as odious. We have been subjected to so many publications of this character since *Psychopathia Sexualis*, *Sexual Inversion*, and kindred works fell into the hands of curious people, that we recognize the form at a glance.

We look for a prefatory apology for each volume by way of explaining that this particular work, at any rate, is published solely in the interests of science. Mr. Carpenter does not disappoint us in this respect; we find on page 9:

The literature of the question . . . has already grown to be very extensive, especially on the Continent, and includes a great quantity of scientific works, medical treatises, literary essays, romances, historical novels, poetry, etc. And it is now generally admitted that some knowledge and enlightened understanding of the subject is greatly needed for the use of certain classes, as, for instance, medical men, teachers, parents, magistrates, judges, and the like.

Whist admitting the unpopularity of the five classes of people Mr. Carpenter has selected as students of his creed

and work, we have sufficient pity for them to attempt to mitigate their punishment by extracting from this book some passages which may suffice to guide each pupil, whether medical man or magistrate, parent or teacher, to an enlightened understanding of the Urnings and Uranianism.

First, then, the derivation of this word "Urning"? Thirty years ago, to be precise, an Austrian writer drew attention to this class of people, amongst whom "the (apparently) masculine person instead of forming a love-unit with a female tended to contract romantic friendships with one of his own sex." So Dr. Ulrichs called the creatures "Urnings" and the custom "Uranianism." This term of endearment amongst foreigners, "Urning," is, we are told, derived quaintly enough from the word *Uranus*; the explanation given is that *Uranos* signifies heaven, the idea being that, according to those who know, "the Uranian love is of a higher order than the ordinary attachment." To avoid any confusion we may here remind our readers that the word "urinal" comes from a different root.

On page 158 of the Appendix we find classification of these eccentrics. (1) *Mannlings*, who tend to love softer and younger specimens of their own sex. (2) *Weiblings*, who love rougher and older men. (3) *Zwischen Urnings*, who love young men, the *Urano-dioning* who is born with a capacity for loving both women and men, and the *Uranianster*, a normal man who has contracted the urning habit.

Krafft-Ebing is cited as insisting upon—

the generally strong sexual equipment of this class of persons, but he hastens to say that their emotional love is also enthusiastic and exalted, and that while bodily congress is desired the special act with which they are vulgarly credited is in most cases repugnant to them.

The Urning loves, defies his male beloved one. For him he is capable of the greatest sacrifice, experiences the torments of unhappiness, often unrequited, love, of faithlessness on his beloved's part, of jealousy, and so forth. His attention is enchained only by the male form. . . . The sight of feminine charms is indifferent to him if not repugnant.

Now we have put before "medical men, teachers, parents, magistrates, judges, and the like," the description Mr. Carpenter gives of these Urnings whose cause he so warmly champions. Most of our readers will prefer to leave them at this point, but since Mr. Carpenter appeals to magistrates and judges, we will cite a few more of his arguments for the defence of those who "form beneath the surface of Society a large class"; for "they suffer severely from the way they are regarded, and in the *manifesto* of a considerable community of such people in Germany, occur the words, 'we are responsive and deeply grateful for the least movement, for every single voice that speaks in our favour in the forum of mankind.'"

We can see Mr. Carpenter holding a pocket-handkerchief before his streaming eyes as he urges us to pity the sorrows of a poor Urning:

To many of them it is a painful thing that in consequence of their peculiar temperament they are, though fond of children, not in the position to found a family.

This appeal *ad misericordiam* may suggest to our magisterial students the plea of the parricide that the court should "pity a poor orphan!" Mr. Carpenter, however, sees a prospect of growing popularity for Urnings from a strictly economic point of view.

Popular opinion has probably been largely influenced by the arbitrary notion that the function of love is limited to child-breding; and that any love not concerned in the propagation of the race must necessarily be of dubious character. And in enforcing this view no doubt the Hebraic and Christian tradition has exercised a powerful influence, dating from far-back times, when the multiplication of the tribe was one of the first duties of its members and one of the first necessities of corporate life. But nowadays, when the need has swung round all the other way, it is not unreasonable to suppose that a similar revolution will take place in people's views of the place and purpose of non-childbearing love.

Those will surely be great days, according to a Swiss writer who is quoted:

Happy indeed is that man who has won a real Urning for his friend; he walks on roses without ever having to fear the thorns.

And then he adds a beautiful touch:

Can there ever be a more perfect sick-nurs: than an Urning?

¹ London: Swan Sonnenschein. Manchester: S. Clarke. 1908. (Cr. 8vo, pp 176. 3s. 6d.)

Mr. Carpenter proceeds to assert that "in the alienation of the sexes from each other, of which complaint is so often made to-day, it must be admitted that Urnings do much to fill the gap," and he goes on to plead that "the love with which we are specially dealing is a very important factor in society, and that its neglect, or its repression, or its vulgar misapprehension may be matters of considerable danger or damage to the commonweal."

That is a passage calculated to disturb the normal mind. But Mr. Carpenter has many shocks and surprises in store for simple folk, for instance:

True Democracy rests more firmly than anywhere else on a sentiment which easily passes the bounds of class and caste, and unites in the closest affection the most estranged ranks of society. It is noticeable how often Uranians of good position and breeding are drawn to rougher types, as of manual labourers, and frequently very permanent alliances grow up in this way, which, although not publicly acknowledged, have a decided influence on social institutions, customs, and political tendencies, and which would have a good deal more influence could they be given a little more scope and recognition. There are cases that I have known (although the ordinary commercial world might hardly believe it) of employers who have managed to attach their workmen, or many of them, very personally to themselves, and whose object in running their businesses was at least as much to provide their employees with a living as themselves; while the latter, feeling this, have responded with their best output. It is possible that something like the guilds and fraternities of the Middle Ages might thus be reconstructed, but on a more intimate and personal basis than in those days; and, indeed, there are not wanting signs that such a reconstruction is actually taking place.

Really, all this is very unsettling, especially when we read that:

Successful love exercises a helpful influence on the Urning. His mental and bodily condition improves, and capacity for work increases.

The passion is, I suppose, so powerful, just because one looks for everything in the loved man—Love, Friendship, Ideal and Sense-satisfaction.

To magistrates and judges we submit the appeal of Mr. Carpenter:

The present state of the Law, both in Germany and Britain—arising as it does partly out of misapprehensions and partly out of the sheer unwillingness of legislators to discuss the question—is really impracticable and unjustifiable. While the Law rightly seeks to prevent acts of violence or public scandal, it is going beyond its province when it attempts to regulate the private and voluntary relations of adult persons to each other. We have said that the homogenic affection is a valuable social force, and, in cases, an indispensable factor of noble human character; yet the Act of 1885 (The Criminal Law Amendment Act) makes almost any familiarity in such cases the possible basis of a criminal charge. Whatever substantial ground the law may have had for previous statutes on this subject—dealing with a specific act—it is surely mistaken in passing so wide-sweeping a condemnation on all relations between male persons (though inconsistently enough making no mention of females). It has undertaken a censorship over private morals (entirely apart from social results) which is beyond its province, and which—even if it were its province—it could not possibly fulfil. It has opened wider than ever before the door to a real, most serious, social evil and crime—that of blackmailing; and it has thrown a shadow over the simplest and most natural expressions of an attachment which may, as we have seen, be of the greatest value in national life.

Mr. Carpenter, however, does not deny "that the homosexual feeling may lead to public abuses of liberty and decency; that it is often improperly indulged; and that much teaching and instruction on the subject is needed."

Mr. Carpenter and his set may, if they please, cherish their grievance against the attitude of the law as to the practices they so warmly advocate; and we would remind them that since England and Germany agree in their condemnation of the cult of Uranus, there are other countries where their society might be welcomed. For instance, how about Tahiti as a health resort? We read:

In the annals of this island are examples of extravagant friendships unsurpassed by the story of Damon and Pythias—in truth much more wonderful—for notwithstanding the devotion to which they led they were frequently entertained at first sight for some stranger from another island.

Surely, however, it would be better for the Urnings to inhabit—we were about to write colonize, but we remember that the chief sadness of their lives is the emphatically non-childbearing essential of their love—some land where their presence might be welcome, and thus serious people in England might be spared the waste of time consumed in reading a low-priced book of no

scientific or literary merit advocating the culture of unnatural and criminal practices, which, while having a pernicious tendency, remains chiefly but not wholly ridiculous. An authority frequently quoted in this book when discussing the criminal side of Uranianism complains "that if familiarities between those of the same sex are made illegal, as immoral, self-abuse ought much more to be so made!"

But we must decline further quotation. The author has definitely unbuttoned himself to any one who likes to pay 3s. 6d. for this book.

HEART DISEASE.

THE small volume, *Graphic Methods in Heart Disease*,² by Dr. JOHN HAY, with an introduction by Dr. JAMES MACKENZIE, printed in clear type, plentifully and well illustrated, has much to recommend it. It contains little or no new matter, but gives a concise account of polygraph work, and is intended to serve as an introduction and guide to those who wish to acquaint themselves with the graphic method. Non-controversial in his style, the writer places before his readers certain facts, with brief interpretations, which are in the main consistent with the views of other workers in the same field in this country. Having outlined the cardiac functions, as now commonly conceived, he gives a summary of Keith's anatomical researches, a detailed description of the new instruments employed clinically and the method of using them, and offers many useful hints to the uninitiated. Normal curves from the jugular veins, apex beat, and other pulsating areas are carefully described. The commoner forms of abnormal cardiac action are exemplified and explained; separate chapters are devoted to "extra-systole" and the "ventricular or nodal form of venous pulse." The eighth chapter acquaints the reader with anomalies of function separately considered. The section allotted to the disturbances of conduction is particularly rich in excellent tracings. The book, ending with a graphic history of a case of mitral stenosis, should fulfil its function—providing a path to the essential facts, and serving as an easy introduction to a subject still in its infancy.

Dr. SCHOTT³ expresses the opinion that the number of heart cases in which direct damage is being done by over-indulgence in athletic exercise is yearly on the increase, and he names cycling as the sport which produces the largest number of such cases. A careful comparison of the effects produced in a healthy individual of 58 years of age, by cycling and walking respectively, showed a marked difference between them in respect of heart dilatation as tested by percussion and x-ray examination. Two points of considerable interest arise out of the perusal of the work before us: First, it confirms the necessity, lately insisted upon by medical officers of schools, for medical examination of all competitors in sports involving great exertion, since latent heart weakness may be wholly unsuspected by the subject of it; and, secondly, it shows that dilatation of the ventricle as seen upon the *post-mortem* table is not an accurate measure of the degree to which the ventricle may have been distended during life. The demonstrable dilatation of the heart of the healthy athlete may often be only temporary, but the corresponding stress upon the weakened heart wall of a less vigorous subject may, and probably often does, lead to a permanent weakening which may have its effect throughout life.

ELECTRICAL INJURIES.

DR. SCHUMACHER, of the University clinic of Zurich, has published a small volume on the subject of accidents brought about through the agency of the electric current.⁴ The work is mainly a clinical study, but it also deals with this important question from the standpoint of medical jurisprudence. It forms an index to the scattered

³ *Zeitschrift für die Untersuchung des Herzens und deren Behandlung*. By Dr. Schott of Naumburg. Fourth edition. Wiesbaden: J. F. Bergmann, 1908. (Sup. roy. 8vo, pp. 59, Taf. III, illustrated. 2s. 3d.)

⁴ *Unfälle durch elektrische Stromstärke. Eine klinische und gerichtlich-medizinische Studie*. Von Dr. E. D. Schumacher. Wiesbaden: J. F. Bergmann, 1908. (Sup. roy. 8vo, pp. 82. 2s. 3d.)

literature on the subject in Germany, France, England and Italy; data are gathered from accident assurance companies on the one hand and medical colleges on the other, and a large number of cases are particularized to enforce the points which the author brings forward. The manner in which electrical currents cause death has given rise to contradictory opinions. The author divides the authorities into three groups, quoting d'Arsonval and Kratzer as affirming that death is due to paralysis of the respiratory centres: Tatum, Oliver, and Bolam and others, that it is brought about by stoppage of the heart's action; and Prevost and Battelli, that either explanation may hold good under different sets of circumstances. For his own part he inclines to the belief, which is shared by most British authorities, that death following upon brief contact with, for example, the poles of an alternating current circuit at high pressure is due primarily to heart paralysis. In this work the effects of lightning discharges are not taken into account, the author confining himself to accidents brought about by artificially generated electricity. Particulars are given of 100 cases of persons killed and injured by electrical currents as a consequence of 98 separate mischances within three years. In the considerable majority of these cases the strength of current involved was more than 1,000 volts, but an appreciable number of accidents, with a fair proportion of deaths, were due to smaller currents ranging from 110 to 250 volts. In 57 cases of supposed death the usual methods of resuscitation were applied, but were successful in 8 only. In dealing with the forensic-medical side of the question, the author illustrates the demands which are made upon the expert knowledge of the "Gerichtsarzt"—that is, the public medico-legal officer. Very often the cause of death is doubtful; moreover, the possibility of suicide must be kept in mind. One fatality is instanced which, instead of being caused by the electrical current as was originally supposed, was found to be due to rupture of the spleen. Even when it is clearly established that electrocution has taken place, the "balance of criminality," if any, has yet to be decided. Negligence or ignorance on the part of the victim is responsible for the largest number of electrical accidents, but it is pointed out that among contributing causes must often be set down makeshift apparatus, insufficient illumination, misleading directions from those in authority, and the absence of protective precautions. Alcohol is cited as answerable for many injuries; not senseless drunkenness, but the bravado stage of intoxication. Those who have to deal with the industrial applications of electricity will find valuable information in what the author has to say about contact risks, the conditions that induce accidents, and the assistance that may be rendered when such accidents occur.

THE DICTIONARY OF NATIONAL BIOGRAPHY.

Since we last referred to the reprint of the *Dictionary of National Biography*,⁵ three volumes, XIV, XV, and XVI, have appeared, containing the articles which filled Volumes XL to XLVIII of the original edition. As has already been stated, the text remains unaltered, save for the correction of certain errors and the revision of some of the biographies. In its new form the *Dictionary* occupies about a third of the shelf space, is as clearly printed, and is at least as convenient to consult as in its earlier form. The three volumes under notice carry the names from Myllar (Andrew), a Burgess of Edinburgh, and the first Scottish printer, who flourished 1503-1508, to Robins (Sanderson), an English divine, who in 1851 published a letter to Lord John Russell on the necessity for State education of the people. Volume XIV contains the biographies of Nelson, by Professor Sir J. K. Laughton, of the Napiers, and of many distinguished Irishmen among the O's. In Volume XV will be found the account of the remarkable career of William Petty, who after teaching anatomy in Oxford, and acting as physician-general to the army in Ireland, surveyed the settled lands in that island, became a politician and an authority on economics, and founded the family of which the Marquis of Lansdowne is now the head. Volume XVI contains the biography of the famous

Radcliffe, physician, for a time, to Queen Anne, and the founder of the library which bears his name at Oxford. Each volume is furnished with an alphabetical index of names, and the *Dictionary* is not only a model of what a work of reference should be, but an exceedingly enticing book to that respectable person, the desultory reader.

NOTES ON BOOKS.

A LARGE volume⁶ which has reached our hands gives a full account of the proceedings of the Society of Medicine and Surgery of Bordeaux during the year 1908. Its contents cover a very wide field. The society appears to meet weekly, and the number of papers recorded is upwards of one hundred. Many of the papers are followed by discussions, but, thanks to the brevity typical of French scientific communications, none of them are fatiguing to read.

The appearance of the *Bibliographica Gymnastica Medica*, by Dr. EDGAR F. CYRIAX,⁷ proves, if proof were wanting, that massage and movement now claim a large share of medical attention. To increase its usefulness, the preface and contents page are printed in three languages. It should be useful to all those who wish to refer to previous works on the various branches of gymnastics, massage, and movement cures.

⁵ *Bulletins et mémoires de la Société de Médecine et de Chirurgie de Bordeaux*. Année 1908. Paris: Masson et Cie. Bordeaux: Feret et Fils. 1909. (Roy. 8vo, pp. 552.)

⁶ *Bibliographica Gymnastica Medica*. By Dr. Edgar F. Cyriax. London: Worcholt, Buchdruckerei. 1909. (Royal 8vo, xxi and 162 pages, containing about 4,000 references to works by about 2,500 authors. 4s.)

THE ANNUAL REPORT OF THE MEDICAL OFFICER TO THE LOCAL GOVERNMENT BOARD.

The annual report of the Medical Officer to the Local Government Board (Dr. Newsholme) for the year 1907-8, has recently been issued.

FOOD INSPECTION.

Dr. Buchanan, Chief Inspector of Foods, presents a report on the work done by his subdepartment during the two years 1906-7 and 1907-8. As a result of representations made to the Board, his assistant, Dr. MacFadden, has made investigations regarding the contamination by lead and arsenic of tartaric acid, citric acid, and cream of tartar. A large number of imported samples were examined and the amounts of lead and arsenic present determined. In several instances the results were unsatisfactory, and it appeared that much of the tartaric acid which arrived in British markets had not been prepared with the care which its use as a food ingredient demanded. In these circumstances it seemed desirable that limits of impurity should be established in regard to lead and arsenic which, account being taken of the ways in which the substances in question are consumed, appeared unlikely to be injurious, and that these, if possible, should not impose an unduly severe task on manufacturers. The limits recommended as guides for trade guarantees and analytical practice in dealing with tartaric and citric acids and cream of tartar were $\frac{1}{10}$ grain per pound of lead and $\frac{1}{100}$ grain per pound of arsenic as arsenious oxide. These recommendations were published in March, 1907, and from information subsequently obtained Dr. Buchanan states that they have been found of practical utility by the trades concerned. There has been a considerable increase in the number of samples of tartaric and citric acids and cream of tartar taken under the Sale of Food and Drugs Acts, and action in these cases has in a number of instances been based on the recommendations of the report.

Dr. Hamill, another of Dr. Buchanan's assistants, has inquired into the adulteration and misdescription of vinegar; he found, amongst other practices calling for remedy, that the adulteration of vinegar by the addition of sulphuric acid was still being carried on. Amongst other subjects which have been engaging the attention of the food inspectors are the addition of preservatives, the

⁵ *Dictionary of National Biography*, Edited by S. Lea. Volumes XIV. Myllar-Owen; XV. Owens-Pookrich; and XVI. Pocock-Robins. London: Smith, Elder, and Co. 1902. (Roy. 8vo, Vol. XIV, pp. 1373; Vol. XV, pp. 1552; and Vol. XVI, pp. 1540. 15s. per volume.)

inspection of imported meat foods, and local administration in regard to the wholesomeness of home prepared foods.

VACCINATION.

Of 935,338 births returned to the Board by the several vaccination officers in England and Wales as registered during the year 1906, the number which, at the time the return was made, had been registered as successfully vaccinated was 686,992 (being 73.4 per cent. of the whole), and the number registered as having died unvaccinated was 88,553 (or 9.5 per cent. of the whole). Of the remaining 159,793 children, 2,203 (or 0.2 per cent. of the whole) had been registered as insusceptible of vaccination, 6 as having contracted small-pox, 14,376 (or 1.5 per cent.) as having their vaccination postponed by medical certificate, and 53,828 (or 5.8 per cent.) as children respecting whom certificates of conscientious objection had been received, leaving 89,380 (or 9.6 per cent.) as "removed," "not to be traced," or otherwise unaccounted for. If from the 935,338 births returned by these officers deduction be first made of the deaths that took place before vaccination, it appears that, of the surviving 846,785 children, there were registered at the time of the return 81.1 per cent. as successfully vaccinated, 0.3 per cent. as either insusceptible of vaccination or as having had small-pox, 1.7 per cent. as under medical certificate of postponement, and 6.4 per cent. as children respecting whom certificates of conscientious objection to vaccination had been obtained, leaving 10.6 per cent. as at that time still unaccounted for as regards vaccination.

Regarding alleged insusceptibility to vaccination, Dr. Leslie Thorne Thorne, director of the animal vaccine establishment at Lamb's Conduit Street, reports that during the existence of this establishment 125,566 consecutive primary vaccinations have been performed there without the occurrence of a single instance of so-called insusceptibility to vaccination having been met with by the officers of the establishment.

Referring to the new Government lymph establishment at Hendon, Dr. Newsholme says:

This establishment has been made as perfect as possible in all its arrangements, and provision has been made in it for the production of greatly increased amounts of lymph in times of emergency.

BACTERIA OF SEWER AIR.

Dr. Andrewes has continued his researches on this subject. In his previous report he brought forward evidence to show that, under many ordinary conditions, characteristic sewage bacteria are demonstrable in sewer and drain air. He found that streptococci in sewer air corresponded in character with those of sewage rather than with those of fresh air, and that bacilli of the colon group, though almost absent from fresh air, could be demonstrated in drain air with no great difficulty, and exhibited biological characters which corresponded exactly with the various bacilli of this group present in sewage. In his present report he has conducted further experiments on "the conditions favouring dissociation of faecal bacteria from sewage during its passage through closed channels in a way to render micro-organisms of this class airborne in emanations from sewers and drains." After considering the methods of bacteriological technique most appropriate for his work, he has satisfied himself that the bile-salt neutral-red lactose agar medium devised by McConkey is well fitted for the detection in drain air of sewage bacteria belonging to the *E. coli* group. Giving a constant exposure of one hour, the number of red colonies arising on plates of this medium has been taken as an index of the relative abundance of sewage bacteria in the air, though it does not reveal the actual number of such bacteria in unit volume of air. Numerous control exposures in fresh air have proved uniformly negative as regards the presence of these bacteria. Applying this mode of investigation to the local drain air of a large public institution and of private dwelling, Dr. Andrewes has shown that sewage bacteria can readily be demonstrated in almost any situation, but that their presence is of a markedly intermittent character. In trapped local inspection chambers the intermittence is more conspicuous than in manholes over main drains. In the latter situation, given even slight degrees of splashing or gurgling, such bacteria seem never

wholly absent from the air; but in a local inspection chamber they may be absent for hours at a time. He considers that in the drainage system of a house or institution in ordinary occupation the determining cause of the presence of sewage bacteria in the drain air is droplet contamination due to splashing, though under other conditions of sewage flow the bursting of bubbles or alternate moistening and drying of the walls may also play a part in the sewage contamination of the air. In droplet contamination the droplets are of extremely minute size, probably less than $\frac{1}{1000}$ c.m. Even in the absence of demonstrable air currents, the influence of droplet contamination extends, in lessening degree, for at least 14 ft. in a horizontal direction, and for at least 12 ft. in a vertical direction, from a focus of slight splashing or gurgling. But the effect of any single act of splashing is very transitory, lasting only for a few minutes. The number of sewage bacteria in the air of drains is influenced by the volume of the sewage flow, which determines the degree of splashing. But as regards the content of drain air in faecal bacteria, the more important factor would appear to be the faecal content of the sewage, and the relative number of lactose fermenting coliform bacilli in the drain air bears a direct relation to the abundance of faecal material in the sewage. Dr. Andrewes points out that his experiments do not justify any conclusion on the important question of the degree to which air currents may convey bacteria dissociated from sewage. This is the problem which underlies the whole question of drain and sewer ventilation and the dangers of the escape of drain air into inhabited houses. He further remarks that there is no evidence that the bacteria which he has so far found in drain air are in themselves harmful. Their importance consists in their being an index of sewage contamination.

ACTION OF LEUCOCYTES ON PYOGENIC COCCI.

Drs. Andrewes and Horder have studied in the rabbit the behaviour of the circulating leucocytes towards pyogenic cocci. In experiments in which known numbers of living pyogenic cocci were introduced, in dangerous dose, directly into the circulation of normal rabbits, they were unable to trace more than a rough correspondence between the size of the dose and the duration of life, owing, apparently, to variations in the individual resistance of the animals. Studying the leucocyte counts of the animals thus infected at short intervals (an hour to fifteen minutes or less), they found the leucocytic response to be highly intermittent. They conclude that the reserves of leucocytes in the bone marrow are, in these circumstances, discharged into the circulation not continuously but in temporary gushes; and they point out that it is easy to overlook a high leucocytic count unless observations are carried out at frequent intervals. Animals which die within one or two days exhibit a failure of leucocytosis before death, but animals which survive longer may show a relatively high leucocytosis up to the time of death, owing, the authors think, to the development of a leucoblastic reaction on the part of the bone marrow. The circulatory leucocytosis is essentially due to increase in the polynuclear neutrophile leucocytes.

When pyococcal vaccines were administered subcutaneously in rabbits, the authors were unable to detect any consequent leucocytosis except in cases where the animals had been previously immunized against some form of pyogenic coccus; but when the vaccines were administered intravenously a pronounced leucocytosis at once ensued. If, in such intravenously vaccinated animals, leucocyte counts are made at short intervals (fifteen to twenty minutes), the leucocytosis is always found to present marked oscillations, suggesting that the bone marrow discharges its reserves in intermittent gushes. This condition is identical with that seen when living pyococci are injected into the circulation. There is experimental evidence that the effect of a single moderate or large dose of pyococcal vaccine intravenously administered is to increase the degree of leucocytic response to subsequent dose, and hence probably to infection with living cocci. The leucocytic response to pyococcal vaccines is essentially due to the polynuclear neutrophile leucocytes. There is nothing to show that the increased

leucocytic response seen after vaccination is in any way specific.

Dr. Andrewes, in a special study of the leucocytes in the rabbit's bone marrow, finds that in normal rabbits submitted to intravenous inoculation with fatal doses of *Staphylococcus aureus*, the number of neutrophile cells in the bone marrow is diminished, though not greatly so, in the animals which die of acute septicæmia within forty-eight hours. If, however, the animal survives for four days or more, there is in all cases a marked neutrophile reaction in the marrow, the number of neutrophile cells per c.mm. being doubled or even quadrupled. This defensive reaction on the part of the bone marrow is also excited by intravenous inoculation with vaccines of killed staphylococci. The known relative immunity which attends such treatment is thus shown to have not merely a humoral (or opsonic) basis, but one which is also anatomical and measurable in terms of the number of neutrophile cells per unit volume of marrow. A correspondence seems to exist between the opsonic value of the serum and the degree of neutrophile reaction in the bone marrow. By too large and too frequently repeated doses of staphylococcus vaccine it is possible to induce an abnormal susceptibility to the coccus in question; this susceptibility is associated with a diminution in the leucoblastic reaction, present in the marrow during the earlier stage of the experiment, no less than with a fall in the staphyloposonic index. In the marrows of animals the resistance of which has been raised by vaccine treatment, but which nevertheless succumb to large doses of virulent cocci, exceedingly high neutrophile counts may be obtained. The bone marrow appears to respond to the presence of *Streptococcus pyogenes* in the same way as to *Staphylococcus aureus*.

Dr. Horder records some preliminary observations upon the prophylactic use of coccus vaccine in rabbits, with particular reference to the amount and frequency of the dose, and the relative advantages of subcutaneous and intravenous inoculation.

PROTECTIVE AGENTS IN MENINGOCOCCUS INFECTIONS.

Drs. Horder and Gordon have issued a preliminary report on this subject. They have tested the value of three anti-meningococcus serums for prolonging the life of rabbits. First they had to deal with the preliminary difficulty arising from the fact that enormous doses of meningococcus are necessary in order to kill a rabbit. This drawback they were able to overcome by making the discovery that, instead of employing a large single dose, smaller doses of meningococcus are given at hourly intervals, a much smaller total amount of culture suffices to kill the animal. It was found, moreover, that this serial method of dosage brought about the death of the animals with great regularity. Employing this method as the criterion of injury, they found that the three serums in question exhibited neither prophylactic nor curative effects. Normal horse serum had, however, some slight value in prolonging the rabbit's life. The authors then proceeded to study vaccination with the meningococcus as a protective measure, and found that rabbits treated with vaccines prepared in various ways withstood, in most cases, a dose of meningococcus fatal to control animals. Encouraged by these results the authors vaccinated themselves with killed meningococcus, in order to satisfy themselves that the material was not injurious. Having established this point, Dr. Horder applied the vaccine in the same way to certain children suffering from cerebro-spinal meningitis, and obtained most promising results.

MASTITIS IN COWS.

In continuation of work commenced a year previously, Dr. Savage reports on the bacteria present in 30 cases of mastitis in cows. These 30 cases, together with 6 cases described in last year's report, showed that in 68 per cent. of the total cases streptococci were present, in 16 per cent. staphylococci, in 3 per cent. *B. tuberculosis*, and in 10 per cent. the origin of the mastitis was doubtful, though in the majority of them it was probably attributable to streptococci. In 60 per cent. of the cases of mastitis associated with streptococci the organisms were of a special type, termed by Dr. Savage the "*Streptococcus mastitidis*." In the remaining 20 per cent. other varieties

of streptococci were found which in several instances were pathogenic for rodents. It was observed that streptococci identical with those associated with the inflammation in the diseased quarters of the udder were found in milk from quarters clinically unaffected by inflammatory or other changes.

Dr. Savage also investigated the streptococci present in 15 cases of human sore throat, and found two types to be particularly prevalent, the more frequently occurring of the two being the *Streptococcus anginosus* type of Andrewes and Horder. Inquiring into the capacity of streptococci to produce mastitis in goats, he found that severe mastitis was produced in three goats infected experimentally with streptococci from cases of bovine mastitis and from a case of ulcerated teats; but in six goats inoculated with streptococci isolated from human sore throats no mastitis resulted. Comparing the human and the bovine streptococci, Dr. Savage says:

Morphologically and culturally the two groups are indistinguishable, but they show a wide divergence when their action towards animals is considered. The mastitis type is non-virulent towards mice and other rodents, but possesses in marked degree the power to cause under inflammation in goats. The anginosus type possesses a considerable virulence towards mice, but is unable to originate mastitis in goats. In other words, an essential difference of functional power separates the types.

GAERTNER BACILLI IN THE ANIMAL INTESTINE.

Dr. Savage has made extensive cultural investigations of thirty-four strains of known members of the Gaertner group of bacilli. The majority of them proved to be culturally identical when eighteen different chemical tests were employed, although they were obtained from a variety of sources—namely, from meat poisoning cases, from cases of paratyphoid fever, and from special diseases of rats, mice, pigeons, and calves. Dr. Savage attaches special importance to the chemical tests by salicin, dulcitol, and saccharose, and doubts if organisms ought to be included amongst the pathogenic members of the Gaertner group when they do not respond to these tests in the same manner as the recognized Gaertner bacilli. The author has also examined the intestinal contents of eighteen healthy and three diseased domestic animals. A number of organisms were found which in many cultural respects closely resembled the meat poisoning bacilli and other organisms of the Gaertner group; but all except one of these could be culturally differentiated by the application of the dulcitol, salicin, and saccharose tests. The remaining bacillus was distinguished by its power to ferment glycerine. The organisms resembling the Gaertner group were further differentiated by their failure to agglutinate with the serum of animals immunized by the different types of Gaertner bacilli. Dr. Savage has been unable to find any evidence in support of the view that recognized pathogenic members of the Gaertner group are inhabitants of the normal animal intestine.

MEDICAL AND SURGICAL APPLIANCES.

A Chloride of Ammonium Inhaler.

THE benefits to be obtained from the use of a neutral nascent ammonium chloride vapour in middle-ear deafness are so well established, and have been so widely recognized, that it is a matter for regret to many medical men to have to discontinue ordering this treatment for their patients, owing to the uncertain and often irritating character of the vapour. The "Kloram" inhaler has been designed by Mr. Frank A. Rogers to obviate this drawback. It has further advantages, which may be briefly summarized as follows: It is simple and strong in construction; it has few working parts; the vapour produced is pure and neutral, and can be easily medicated and rendered antiseptic; furthermore, the inhaler is easily managed by the patient, it is self-contained within a case from which it need not be removed when required for use, and in which it can be readily stored when not in use; the directions for charging, using, and cleaning are given in the case, are clear and unmistakable, and everything necessary for a prolonged course of treatment is provided at the moderate and inclusive price of 7s. 6d., which in view of the time and trouble that have evidently been expended in perfecting the apparatus cannot be regarded as unreasonable.

THE INSTITUTE OF PHYSIOLOGY, UNIVERSITY COLLEGE.

THE new Institute of Physiology, an illustrated account of which was given in the JOURNAL of June 12th, was formally opened on Friday, June 18th, by the Right Hon. R. B. Haldane, Secretary of State for War. Professor M. J. M. HILL, Vice-Chancellor of the University of London, presided, and there was a large attendance. The number and splendour of the academic robes gave variety of colour to the scene. Among those present were Lord REAY (Chairman of University College), Lord Cromer, Lord Strathcona, Sir Archibald Geikie (President of the Royal Society), Sir Richard Douglas Powell (President of the Royal College of Physicians), Mr. Henry Morris (President of the Royal College of Surgeons), Sir William Church (President of the Royal Society of Medicine), Dr. H. A. Miers (Principal of the University of London), Sir John Tweedy, Sir Dyce Duckworth, Dr. H. T. Bovey (Rector of the Imperial College of Science), Sir Philip Magnus, M.P., Mr. H. T. Butler, Sir John Batty Tuke, M.P., Sir William Ramsay, Professor Gotch (Oxford), Dr. Gaskell and Professor Langley (Cambridge), Professor Schifer, Professor Verworn (Goettingen), Sir Victor Horsley, Colonel Lockwood, Sir William Gowers, Sir Thomas Barlow, Professor Halliburton, and the Hon. Sydney Holland.

After an introductory speech by Lord REAY,

Mr. HALDANE, who had previously inspected the laboratories, congratulated Professor Starling on having an equipment attached to the Chair of Physiology which put him in the first position in that respect among the universities of the world. He went on to speak of the vast development of university education in this country during the last twenty years. The founding of the University of Wales in 1893 had been followed by the incorporation of the universities of Birmingham, London, Liverpool, Manchester, Leeds, Sheffield, and Bristol. Ireland had now got two more universities; Scotland had always had four. In the United Kingdom there were now eighteen universities. Further, the development of university colleges—Reading, for example—had been very marked; and there had grown up in the last twenty years the great technical colleges. If the nation continued at that pace he should have no fear with regard to the future of the highest kind of education. The present condition of primary education stood in the way of the organization of secondary schools, and until these were organized the universities could not be given their properly defined place. Secondary education was perhaps the most backward in this country, and some of the best-known public schools were the slowest to see the wisdom of adopting leaving certificates and sending their pupils to the universities properly equipped. He hoped that people were waking up to the claims of university colleges. When he read, as he did with great interest, the obituary and testamentary records in the *Times* every day, he was delighted to observe that testators were more prone than they used to be to leave large sums for higher education. He hoped that tendency would grow. Mr. Haldane then declared the new institute open.

A vote of thanks was proposed by the PRESIDENT OF THE ROYAL SOCIETY, seconded by the PRINCIPAL OF THE UNIVERSITY, and supported by Professor STARLING, who spoke on behalf of the staff of the Institute. He referred to the presence of so many leading members of the medical profession and biologists representing the chief universities of the British Empire as well as of the Continent. "Those of our colleagues," he said, "who come from foreign countries to testify to the solidarity of science throughout the world, may perhaps have wondered why we should have invited the Minister of War to open these laboratories, and why this ceremony should be made at the same time an occasion for a military parade. They perhaps had not known that Mr. Haldane, in addition to the responsible position which he holds in the Cabinet, has for many years discharged the self-imposed duties of a Minister for Universities, and that his persistent advocacy of the cause of higher education, is due largely to the great development in university work in England, which has taken place during the last decade; nor are the two roles so ably fulfilled by Mr. Haldane incompatible, for, after all, in this attempt to make voluntary training universal, beginning with the universities, he is teaching an individualistic race the great lesson which has to be learnt by every community

—namely, the lesson of service. That, after all, is the aim of all education; on the learning of that lesson depends the man's future value as a citizen; on our success in inculcating that spirit in the new generation depends the survival or failure of our race. But I would have you see, as Mr. Haldane sees, that this devotion, this spirit of service to a national ideal, is but a phase in the development of the race. The same lesson of service must be learnt before we can hope to grapple successfully with the problems presented to us in our laboratories." "Already," he continued, "throughout the armed camps of Europe we have an ever-increasing body of men who in their laboratories devoted their lives to the service not of their nation alone but of the whole of humanity. It is these men who have honoured us by their presence to-day at the dedication of this home of science, this temple for the service of man. It is these men who, forming now a brotherhood within the nations, are working for the final brotherhood of all nations. That, I take it, is the ultimate goal of the eminent philosopher and statesman who to-day visits us in the guise of a Minister of War, who can see through and beyond the national army which he is creating to that further development which must be the final outcome of his efforts, when civilized man, like the science which is its leader, shall be but one nation, and these battalions but a memory of the playthings of man's childhood." Professor Starling concluded by saying that physiology was a pure science. Those who pursued it had as their immediate object merely the increase of human knowledge. They claimed that this increase was for the good of mankind, however remote the subject of their investigations might seem from the immediate needs of suffering humanity. It was only now and then, as it were, by chance, that their physiological researches resulted in some immediate method of successful treatment of disease. The greater part was the laying of the foundation on which the medicine of to-day and to-morrow must be built, and without which all practice must be pure empiricism. It was upon the medical profession they called to bear witness to the truth of this statement.

INSPECTION OF OFFICERS' TRAINING CORPS.

After the ceremony Mr. Haldane reviewed the University of London Training Corps drawn up in the south quadrangle in front of the institute. He expressed himself as highly pleased with the appearance of the men.

DINNER TO DR. J. F. W. TATHAM.

DR. J. F. W. TATHAM was entertained at dinner at the Grand Hotel, London, on June 17th, on the occasion of his approaching retirement from the position of Superintendent of Statistics, General Register Office, which he has held since 1893.

Sir SHIRLEY MURPHY was in the chair, and amongst those present were the Registrar-General (Sir William Dunbar), Mr. R. Brudenell Carter, Drs. Sidney Coupland, Arthur Newsholme, Franklin Parsons, R. Bruce Low, B. A. Whitelegg, C.B., G. Newman, J. C. McVail, A. K. Chalmers, R. Deane Sweeting, S. Monckton Copeman, F.R.S., Wilfred Fletcher, H. Timbrell Bulstrode, G. S. Buchanan, Squire Sprigge, Colonel Lane Nottet, Colonel Firth, Mr. A. C. Wares, Mr. G. Udney Yule, Lieutenant-Colonel W. Grant Macpherson, C.M.G., Mr. R. O. K. Lempert (representing Dr. W. N. Shaw, F.R.S.), Drs. J. Kerr, W. J. Simpson, Dawson Williams, J. F. J. Sykes, T. Hugh Dickson, F. E. Fremantle, R. Musgrave Craven, G. Millson, Paddock Bate, J. Niven, S. Barwise, W. A. Bond, C. W. F. Young, George Reid, J. M. Martin, Bushell Anningson, A. A. Mussen (representing Dr. E. W. Hops), J. F. Payne, F. J. Allan, T. H. C. Stevenson, Kenneth Goadby, Mr. George King, Mr. George H. Day, together with Drs. W. H. Hamer and Herbert Jones, who acted as secretaries.

The loyal toasts having been honoured, the CHAEMAN proposed "The Health of Dr. Tatham." He spoke of his long connexion with the public health service as Medical Officer of Health of Salford and of the city of Manchester, and referred to his sixteen years in the office of the Registrar-General as the crowning work of his life. Though there might be some persons who would say that they had never heard of Dr. Tatham, every one engaged in public health work had every good reason for knowing how greatly this country was indebted to him.

He had succeeded in office two eminent men in Dr. Farr and Dr. Ogle. Dr. Farr had realized what could be made of the classification of diseases, and had produced a system which was so able that it only required modification in the manner subsequently adopted by Dr. Ogle and Dr. Tatham to bring it into line with modern scientific ideas. This work of the Registrar-General and of Dr. Tatham had, in his opinion, been a very active cause in diminishing the death-rate in this country. The tables that had been published in the reports of the Registrar-General constituted lessons of the very first importance, and there was no doubt that a great deal of light had been thrown on the causes of death among infants by the tables on infantile mortality. When the system of death registration was proposed in the early Seventies it was not intended at first that the cause of death should be included in the information recorded, and the requirement was only inserted by the House of Lords. In 1874 medical certification of the cause of death became compulsory, but prior to that date Dr. Farr had suggested to the Presidents of the Royal Colleges of Physicians and Surgeons and the Master of the Apothecaries Society that medical practitioners should be invited to certify voluntarily as to the cause of death. It might be said that diagnosis was the best guess that could be made in the circumstances, and Dr. Tatham and the Registrar-General had to accept the diagnoses which reached them. In order to clear up doubts in certain cases, the General Register Office had introduced a system of addressing an inquiry to medical practitioners, and as many as 5,000 such letters were sent out each year, involving a large amount of labour, which was, however, well rewarded by the more exact results obtained. Sir Shirley reminded his audience of the important part which Dr. Tatham had taken in instituting the system of interchange of records of infectious diseases, a work which he had to relinquish upon taking up his duties at Somerset House, but which was considered of such importance that it was taken over by the Local Government Board. Great changes had taken place in medical knowledge during the time that Dr. Tatham had been in the General Register Office, but he had been able at all times to place the best medical knowledge at the disposal of the Registrar-General. Outside the actual work of his office, Dr. Tatham had rendered excellent service to the State as chairman of the Statistical Committee of the Cancer Research Fund, and also as a member of the Departmental Committee on Physical Deterioration. Sir Shirley recalled with satisfaction the fact that so many of the responsible positions in the State service were recruited from the public health service, instancing Dr. Newsholme, Dr. Parsons, and Dr. Bruce Low at the Local Government Board, Dr. Whitelegge at the Home Office, and Dr. Newman at the Board of Education. He finally referred to Dr. Tatham as the willing servant of those engaged in public health work, and said that he had always been so ready to render help to all those who asked for it that they had begun to feel that they had a right to it.

Sir WILLIAM DUNBAR said that he had the permission of the Chairman to say how glad he was to be there to show his appreciation of the services to the State which Dr. Tatham had rendered, and also to thank the medical profession for the many ways in which they had helped him. He was in the fortunate position of being able to confirm as few people could all that had been said of Dr. Tatham's work. The seven years he had himself spent at Somerset House had been made appreciably pleasanter and happier because of his association with such an able colleague. He himself was not a statistician, so that it would have been quite impossible for him to have prepared his report on the last census without the assistance of Dr. Tatham. Mr. Noel Humphreys, and Mr. Waters. The declining birth-rate had caused a great deal of concern to many persons whose pessimistic views he did not endorse, and he could never agree with those who thought that England was going downhill.

Dr. TATHAM, in responding, said that he felt he did not owe the honour that had been done him to any merits of his own, but to the general feeling of comradeship that existed between members of the medical profession and himself. Statistics must always, he said, be defective, and to reduce those defects had ever been his first aim. Referring to the certification of the causes of death he said

that the experience of the past sixteen years had led him to form a very high opinion of the care which medical men took in certifying those causes. Greater accuracy had certainly been secured from the replies which were received to the inquiries which were sent out from the Registrar-General's office for the purpose of clearing up doubtful points. Our own statistics, he maintained, would compare most favourably with those of foreign countries. He concluded by expressing the hope that his successor would be as fortunate as he had been in securing the loyal and disinterested support not only of his colleagues in the profession but of all the staff of the Registrar-General's office.

Dr. WHITELEGGE proposed the health of the Chairman, who responded.

MOTOR CARS FOR MEDICAL MEN.

COST OF RUNNING.

VIATOR writes: I agree with Dr. J. Bernard Wall that there must be something "radically wrong" if motor car expenses run up as some of your correspondents state. I have used motors now for more than five years, and find them cheaper than horses, while they are more satisfactory in every way. The expenses are very largely under the control of the owner. If he gets a good car to start with, and carefully studies the book of instructions which most makers supply, and sees that these instructions are really carried out, he will, I think, be surprised to find how low the expenses are. My own experience is that motors have lessened my expenses and increased my receipts.

NESTOR writes: The correspondence on the expenses of a motor car is interesting, and, taken in conjunction with the article on the financial prospects of the profession, I am rather inclined to agree with your original correspondent as to the difficulty of keeping a banking account and running a motor car. Thus a country practice making £900 gross receipts on an average may safely be considered a good practice. I think it is obvious that the stable expenses of such a practice should not exceed £150 a year at the most. Now "P. L. J. 31" gives his annual expenses for an 8-h.p. two-seated Greenglade, including depreciation, as £103 8s. I am sure he has underestimated depreciation, as I cannot believe he would get £100 at the end of five years for a car which originally cost £220. Probably he would get £50.

Again, some of your correspondents mention the necessity of having two cars. I can well imagine it, but the cost would be enormous to most men. In other words, to keep a small car, including depreciation, and adding the wear of a groom-chauffeur, would certainly amount to £150 a year or over. For the same money or less two horses, or perhaps, better still, a horse and a motor-cycle could be kept.

I think it is quite clear that motoring under the most lucky conditions is costly, and that men in practice are evidently increasing their running expenses without any corresponding gain in receipts. And so your original correspondent is not far wrong in his contention that running motor cars (apparently insufficient) is not compatible with keeping a banking account, and this taking a mileage of 6,000 miles a year.

CARS FOR THE TROPICS.

INCORAMUS desires to learn of a good make of motor car (8 h.p.) suitable for Rangoon or Madras, and whether a good second-hand car could be obtained for £100.

THE first annual dinner of the Society of Tropical Medicine and Hygiene was held on June 18th at the Trocadero Restaurant, London, Professor Ronald Ross, C.B., F.R.S., the newly-elected President, being in the chair. A large number of Fellows were present, and also many well-known guests, including Sir Archibald Geikie, President of the Royal Society; Mr. Henry Morris, President of the Royal College of Surgeons; Professor Count Mörner of Sweden, Colonel Seely, D.S.O., M.P., Under Secretary of State for the Colonies; Mr. Ramsay MacDonald, M.P.; Sir Alfred Jones, K.C.V.O., and Sir William Treacher. After the loyal toasts had been drunk, the toast of "The Society" was proposed by Colonel Seely and Sir Alfred Jones, the Chairman responding. In a very interesting speech, Colonel Seely made sympathetic reference to the men who had laid down their lives in the pursuit of tropical research abroad, and also indicated the intense interest the Colonial Office took in the schools and the work they were doing. Sir Alfred Jones spoke as to the progress sanitation had made in Africa, and what had been done to ameliorate the lot of the natives and white people living in these areas. The Britisher, he said, liked to get his twenty shillings for his pound, and by making these places healthier he would get it or more. Sir Patrick Manson proposed the health of the guests, and after responses had been made by Sir Archibald Geikie, Mr. Henry Morris, and Professor Count Mörner, the proceedings were brought to a close by the proposal of the Chairman's health by Mr. Ramsay MacDonald, M.P. The society, though only started two years ago, is now in a very flourishing condition, its Fellows numbering over 320.

EXPERIMENTS ON LIVING ANIMALS.

The return showing the number of experiments on living animals during the year 1908, under licences granted under the Act 39 and 40 Vict., c. 77, has just been issued.

ENGLAND AND SCOTLAND.

Professor Thane's report contains the names of all "registered places." Three new places were registered for the performance of experiments, and three places were removed from the register during the year. All licensees were restricted to the registered place or places specified on their licences, with the exception of those who were permitted to perform inoculation experiments in places other than a "registered place," with the object of studying outbreaks of disease occurring in remote districts or under circumstances rendering it impracticable to perform the experiment in a "registered place." The names of all the persons who held licences during 1908 are given. The total number of licensees was 453. The reports furnished by the licensees show that 126 licensees performed no experiments. The number and nature of the experiments returned by each licensee are also stated. The experiments are, as usual, set forth in a Table (IV), which is divided into two parts—A and B—for the purpose of separating experiments which were performed without anaesthetics from experiments in which anaesthetics were used.

Number of Experiments.

The total number of experiments included in Table IV (A) is 2,851.

Of these there were performed :

Under Licence alone	1,452
" Certificate C	156
" Certificate B	989
" Certificate B + EE	247
" Certificate F	7

Table IV (B) is devoted entirely to inoculations, hypodermic injections, and some few other proceedings, performed without anaesthetics. It includes 85,783 experiments, whereof there were performed :

Under Certificate A	85,121
" Certificate A + E	460
" Certificate A + F	202

The total number of experiments was 88,634, being 15,260 more than in 1907; the increase in the number of experiments included in Table IV (A) is 271, and in Table IV (B) 14,989.

The Use of Anaesthetics.

The larger part of the experiments included in Table IV, namely, all performed under licence alone, under Certificate C, and under Certificate F (without A or B), 1,615 in number, come under the provisions of the Act that the animal must be kept under an anaesthetic during the whole of the experiment, and must, if the pain is likely to continue after the effect of the anaesthetic has ceased, or if any serious injury has been inflicted on the animal, be killed before it recovers from the influence of the anaesthetic.

In the experiments performed under Certificate B, or B linked with EE, 1,236 in number, the initial operations are performed under anaesthetics, from the influence of which the animals are allowed to recover. The operations must be performed antiseptically, so that the healing of the wounds shall, as far as possible, take place without pain. If suppuration occurs, the animal must be killed. After the healing of the wounds, the animals are not even generally in pain.

In the event of a subsequent operation being necessary in an experiment performed under Certificate B, or B linked with EE, a condition is attached to the licence requiring all operative procedures to be carried out under anaesthetics of sufficient power to prevent the animal feeling pain; and no observations or stimulations of a character to cause pain are allowed to be made unless the animals are anaesthetized.

In no case has a cutting operation more severe than a superficial venesection been allowed to be performed without anaesthetics.

The experiments included in Table IV (B), 85,783 in number, were all performed without anaesthetics. They were mostly inoculations, but a few were feeding experiments, or the administration of various substances by the

mouth or by inhalation, or the abstraction of blood by puncture or simple venesection. In no instance has a certificate dispensing with the use of anaesthetics been allowed for an experiment involving a serious operation. Inoculations into deep parts, involving a preliminary incision in order to expose the part into which the inoculation is to be made, are required to be performed under anaesthetics.

Professor Thane goes on to say :

It will be seen that the operative procedures in experiments performed under Certificate A, without anaesthetics, are only such as are attended by no considerable, if appreciable, pain. The certificate is, in fact, not required to cover these proceedings, but to allow of the subsequent course of the experiment. The experiment lasts during the whole time from the administration of the drug, or injection, until the animal recovers from the effects, if any, or dies, or is killed, a period possibly extending over several days, or even weeks. The substance administered may give rise to poisoning, or set up a condition of disease, either of which may lead to a fatal termination. To administer to an animal such a poison as diphtheria toxin, for example, or to induce such a disease as tuberculosis, although it may not be accompanied by acute suffering, is held to be a proceeding "calculated to give pain," and therefore experiments of the kind referred to come within the scope of the Act 39 and 40 Vict., c. 77. The Act provides that, unless a special certificate be obtained, the animal must be kept under an anaesthetic during the whole of the experiment; and it is to allow the animal to be kept without an anaesthetic during the time required for the development of the results of the administration that Certificate A is given and allowed in these cases.

It must not be assumed that the animal is in pain during the whole of this time. In cases of prolonged action of an injected substance, even when ending fatally, the animal is generally apparently well, and takes its food as usual, until a short time before death. The state of illness may last only a very few hours, and in some cases it is not observed at all.

In a very large number of the experiments included in Table IV (B) the results are negative, and the animals suffer no inconvenience whatever from the inoculation. These experiments are therefore entirely painless.

In the event of pain ensuing as the result of an inoculation, a condition attached to the licence requires that the animal shall be killed under anaesthetics as soon as the main result of the experiment has been attained.

Explanation of Increase in Experiments.

It is explained that the increase in the number of experiments in Table IV (B), 1908, when compared with that of 1907, namely, 14,989, is mainly due to the 12,500 experiments performed on behalf of the Royal Commission on Sewage Disposal. These experiments consisted in exposing the ova and young of fish to the influence of effluents in different stages of purification and dilution.

During the year 1908, 40,870 experiments were performed at three institutions in the course of cancer investigations. Of these 233 are in Table IV (A), and 40,637 in Table IV (B). The latter were almost entirely inoculations into mice.

Experiments for Government and Public Bodies.

A large number of experiments, almost wholly simple inoculations and similar proceedings, contained in Table IV (B), were performed either on behalf of official bodies, with a view to the preservation of the public health, or directly for the diagnosis and treatment of disease. Several county councils and municipal corporations have their own laboratories in which bacteriological investigations are carried on, including the necessary tests on living animals; and many others have arrangements by which similar observations are made on their behalf in the laboratories of universities, colleges, and other institutions. A sewage farm is registered as a place in which experiments on living animals may be performed in order that the character of the effluent may be tested by its effects on the health of fish. The Board of Agriculture and Fisheries has a laboratory which is registered for the performance of experiments having for their object the detection and study of the diseases of animals. In other places experiments have been made on behalf of the Home Office, the War Office, the Colonial Office, the Local Government Board, the Metropolitan Asylums Board, the Royal Commission on Tuberculosis, the Advisory Committee for Plague Investigation in India, and the Tropical Diseases Committee of the Royal Society. Sixty-six licensees return over 12,000 experiments which were performed for Government Departments, county councils, municipal corporations, or other public health authorities; 2,332 experiments were performed by three licensees for

the Royal Commission on Tuberculosis; and thirteen licensees performed nearly 5,000 experiments for the preparation and testing of antitoxic serums and vaccines, and for the testing and standardizing of drugs.

Inspections.

During the year the usual inspections of registered places were made by Professor Thane and by Sir James Russell. They saw numerous animals under experiment, both of those coming into Table IV (A) and of those coming into Table IV (B); they everywhere found the animals suitably lodged and well cared for, and the licensees attentive to the requirements of the Act, as well as to the conditions appended to their licences by the Secretary of State.

Irregularities.

The irregularities which occurred during the year were few, and all arose from misunderstanding or inadvertence with respect to the extent or application of certificates. They were as follows:

One licensee performed 186 inoculation experiments in excess of the number for which the Certificate A had been given.

One licensee performed feeding experiments on seven puppies, one kitten, and two rodents without obtaining the necessary Certificate A (E).

One licensee exceeded the terms of his certificate, which authorized the abstraction of small quantities of blood, by bleeding to a considerable amount.

One licensee who held Certificate B, authorizing exposure to x rays and the application of heat to the skin under anaesthetics, carried out these procedures without an anaesthetic.

Two licensees holding Certificate A, authorizing experiments without anaesthetics, performed feeding experiments which were not indicated in their certificates.

By direction of the Secretary of State a suitable admonition was addressed to each of these licensees.

IRELAND.

Sir W. Thornley Stoker reports that in 1908 there were in Ireland fifteen registered places; in three of them no person was licensed to perform experiments during the year 1908. Twenty licensees were in force during the year, of which thirteen were in existence at the beginning of the year, and seven were new licences issued during the year.

Number of Experiments.

The experiments performed were 390 in number; 42 under licence alone, and 348 under certificates. Sixteen licensees performed experiments. Twenty licensees held 37 certificates, of whom 14 performed experiments, namely:

Under Certificate A	322
" Certificate C	21
" Certificate E + A	2
" Certificate E + B	1
" Certificate F	2

Animals Used.

The animals experimented on were as follows: Guinea-pigs, 208; mice, 113; rabbits, 38; dogs, 15; cats, 3; sheep, 3; cattle, 3; fowl, 3; horses, 2; goat, 1; rat, 1.

Nature of Experiments.

The experiments were very various, and included studies of the mechanism of respiration, blood pressure, and cardiography. The differentiation of various forms of blood stains, the diagnosis of cattle diseases, the consideration of questions concerning food poisoning, of typhoid fever, of the actions of various drugs on the heart and blood, of tuberculous milk, of the action of the vagus nerve, of the diagnosis of urinary diseases, were all matters considered. The study of meningeal cocci, of gland secretion, of the etiology of pulmonary tuberculosis, and cerebro-spinal meningitis of the epidemic form, were also subjects of investigation.

No Abuse.

The work done in Ireland under the Act was, in the inspector's opinion, free from abuse, and was sincere and well intentioned. The increase in the number of licensees and of their experiments is to be attributed to the study of new investigations and treatments of disease by means of antitoxins, serums, and vaccines. This branch of physiological and pathological work, says the inspector, is of great value and importance, is unattended by more than very slight pain, and promises even greater results in the future than it has achieved in the past.

THE ROYAL COMMISSION ON THE POOR LAW AND THE RELIEF OF DISTRESS.

INFANT MORTALITY IN WORKHOUSES.

It is a somewhat unusual thing for a Government Department to issue a memorandum finding fault with the statistics and deductions given in a report by a Royal Commission, but a few weeks ago the Local Government Board issued to Parliament a memorandum distinctly controverting the statistics about infant mortality in workhouses given by the Minority Report of the Poor Law Commission. Sufficient time has now elapsed, but the only reply, by one of the signatories to the Minority Report, has been a reiteration of the statistics and the deductions from them. There has been no attempt to deal with the fundamental objections of the Local Government Board against the reliability of the statistics, and it would seem as if the force of these objections and the seriousness of issuing figures which are open to the charge of being misleading was hardly realized. The seriousness of the matter is all the greater because the figures and the method of argument adopted by the Minority Report would involve a charge against not only the workhouses, but against some of the best conducted maternity hospitals of the metropolis. This may not have been intended, but it is a logical deduction. It would therefore seem to be necessary again to emphasize in an elementary way the contention of the Local Government Board that the statistics on infant mortality given by the Minority Report are quite unreliable, and from their very nature give no warrant by themselves for the conclusions drawn from them.

It is not necessary again to quote at length from the Minority Report, as this has already been done in the issue of the JOURNAL for February 27th, pp. 546-8, to which and to the report itself reference should be made, but a brief summary may be convenient. It appears that something like 11,000 children are born every year in the workhouses of England and Wales, and a member of the Commission was able to get some information from 450 workhouses in which 8,483 infants were born in 1907. We are told that "out of these 8,483 infants no fewer than 1,050 actually died on the premises before attaining one year." This is about 123 per 1,000, but of course this figure is quite useless for so floating a population, and in order to get statistics that it was thought might be compared with statistics given by the Registrar-General for the whole population, the Minority Commissioners hit on the extraordinary and fallacious device of assuming "that those who left the workhouse within the year had a death-rate equal to those remaining in the institution," and having made this assumption they conclude as follows:

The result appears to us somewhat startling. The infantile mortality in the population as a whole, exposed to all the dangers of inadequate medical attendance and nursing, lack of sufficient food, warmth, and care, and parental ignorance and neglect, is admittedly excessive. The corresponding mortality among the infants in the Poor Law institutions, where all these dangers may be supposed to be absent, is between two and three times as great. Out of every 1,000 babies born in the population at large, 25 die within a week, and 132 are dead by the end of the first year. For every 1,000 children born in the Poor Law institutions 40 or 45 die within a week, and, assuming the mortality among those who are discharged to be the same as those remaining, no fewer than 268 or 392 will be found to have died by the end of the year, the number varying according to whether we take the experience of the Poor Law institutions for legitimates or for illegitimates in the metropolis or elsewhere.

Now it is evident that while accurate figures are obtainable for the first week or two, as all the infants remain on the premises for about that time, the figures for the annual mortality are, on the other hand, on quite a different footing, depending on an assumption that is open to question. Separate consideration is therefore needed.

Taking the annual figures then first, we are told that "more than half the mothers discharged themselves within a month, one-eighth of them indeed within a fortnight." Others of course may be assumed to have taken their discharge at varying times within the year, so that comparatively few would remain for the whole year. Further, it is practically certain that infants' ailing from

birth would be retained in the workhouse, while the strong mothers with their strong infants would be more likely to take their discharge. Thus the workhouse would retain most of the bad lives and discharge most of the good lives. Again, of the healthy infants discharged into good homes, only few would be readmitted to the workhouse; their death-rate would be low, and it is altogether unwarrantable to assume without reason that their death-rate is equal to that of those retained in the workhouse. On the other hand, many of the infants discharged would be taken to the worst of slum homes where they would be badly clothed, badly nursed, and badly fed, and when their health had been ruined and their death practically determined by conditions *altogether outside the workhouse* many of them would be returned to the workhouse when it was too late to save them. In this way, then, the workhouse would be not simply a maternity home or an ordinary nursing home, but also a sort of hospital for incurables, whose death-rate is almost beyond control. In addition to all this, the general type and character of the parents is such that we might naturally expect that the death-rate of the infants would be high, however efficient the workhouse might be. In the House of Commons recently Mr. Burns said, "It ought to be remembered that many of the mothers of the children born in workhouses had been cruelly beaten, overworked, and badly treated generally before their admission, and the offspring of such mothers could not be expected to be as healthy as children who were differently placed." The report itself acknowledges this in quoting the words of an inspector describing the character of the mothers:

Poor girls refused the shelter of their own homes in time of trouble; syphilitic patients; women who have been knocked about, neglected, and ill-treated up to the last minute; cases actually in labour when admitted; in time, all sorts and conditions of poor women, who have nowhere else to go, find their way to the Poor Law maternity wards.

And yet, though the report acknowledges this and admits the shortcomings of its statistics, it still harps on the death-rate as if the workhouses were responsible for it. The report further compares the annual infant mortality of 10 workhouses in which 493 infants were born with another 10 in which 333 were born. In the first 10 the annual infant mortality was 30 per 1,000, and in the second 10 it was 330 per 1,000. It is implied here that the first ten were models of maternity and nursing homes, and that the second ten, having a mortality eleven times as high, must have been everything that is bad. But nothing of the sort is proved by the figures alone; they are open to the same fallacies as are noted above, and, in addition, the varying character of the contributory population is ignored. As the Local Government Board points out, very different results may, to take an extreme example, be expected in workhouses where healthy farm servants are the inmates from those where only slum dwellers are dealt with. Common fairness of debate ought to have prevented the use of statistics which are inherently so unreliable and misleading. To bolster up even a good case with arguments which might catch the unthinking but the fallaciousness of which is obvious on the slightest examination, is apt to throw some suspicion on the whole case, which may be undeserved.

Again, dealing with the deaths that occur within the first week or two after confinement, we are told that while in the general population 25 out of every 1,000 born die within a week, in the workhouses 40 to 45 die. This is confirmed by figures furnished by the Local Government Board for the whole of the metropolitan Poor Law institutions, which show that the infant mortality during the first week is 42.2 per 1,000 births, which is nearly double the corresponding rate for the general population of London. But a totally different complexion is put on the figures from what the Minority Report implies when the causes of the deaths during the first week are examined. The Local Government Board finds that over 50 per cent. of the deaths are due to premature birth, 41 per cent. to congenital defects, atrophy, debility, marasmus, and inanition, 2.6 per cent. to congenital syphilis, 3.5 per cent. to difficult labour and asphyxia, and 1.8 per cent. to convulsions—all causes mostly due to prenatal and maternal conditions entirely independent and unconnected with the workhouses. In other words, it is the character of the

material that is at fault, not either the ability or the care bestowed on it in the workhouses. In the second week of life the death-rate was actually slightly lower in the workhouses than in the general population; but even so early as this the numbers remaining in the workhouses were becoming too small for any trustworthy statistics to be based on them, as half the children leave the institutions within three weeks of birth. After that time the deaths include a proportion of infants readmitted after being exposed to all sorts of injurious conditions outside the workhouses.

The Minority Report points to the Plaistow Maternity Charity, which deals with women in their own homes in West Ham, and has an infant mortality of only 15.3 per 1,000 births in the first fortnight, while the four large voluntary maternity hospitals in London have an average rate of 30 per 1,000, and the Poor Law institutions of the metropolis a rate of 46 to 47. If the Minority argument is of any value it would show that the Plaistow nurses are able to manage better in the wretched slum houses of West Ham than in the well-equipped voluntary hospitals, with all their appliances and competent attendance. But, of course, nothing of the kind is proved by the figures. The different results may be explained by the different character of the patients, and no comparison of figures is of the slightest value. Labours conducted in the patients' homes will be mostly normal, while the hospitals get the most dangerous cases where the infants are most likely to suffer. Of so little value are such numerical comparisons that it may easily be the case that a hospital with a death-rate of 50 may really be better managed and more efficient than another with a death-rate of only 10, or, to take a concrete case, it by no means follows that the General Lying-in Hospital, which has an infant death-rate of 59 per 1,000 in the first fortnight, is worse conducted than the City of London Lying-in Hospital, where the death-rate is only 20.4. If the number of patients be small and the nature of the cases be not taken into account, the fallacy of any figures ought to be obvious, and to say that "it cannot be right that there should be workhouses in which 40 per cent. of the babies die within the year" is a statement that shows an utter failure to grasp the significance of varying conditions. Such a death-rate is deplorable, but it may not be the fault of the workhouses at all.

These remarks must not be taken to denote any desire to palliate or excuse any bad management of either lying-in wards or nurseries. Their only object is to point out that the extraneous conditions vary so immensely, not only in different workhouses, but in the same workhouse at different times, that it is practically impossible to frame any statistics that can be fairly comparable with one another, and the demand for such statistics by the "State Children's Association" cannot be gratified. There may be perfect management with high death-rate, and bad management with low death-rate. The only test of efficiency is careful inspection by competent experts. Numerous witnesses whose ability to judge is unquestioned have testified that the management in some workhouses is lamentably bad both in lying-in wards and nurseries, and it is a matter for satisfaction that Mr. Burns has assured the House of Commons that special investigations were being made by the medical department of the Local Government Board, and that a report would be issued. Meanwhile, when Dr. Downes and Dr. McVail testify to the "admirable work and the extraordinary success" of some workhouses in their maternity wards and nurseries, it is not fair to assume for one moment that they are attempting to whitewash the faults of others. Nothing will ever be gained by exaggeration. It is indeed an open question whether the wholesale condemnation of the lying-in wards and nurseries may not have the apparent effect of raising their death-rates by deterring poor women of good character from entering, while the prostitutes and women of the worst classes whose babies are more likely to die, will enter as freely as ever. The workhouse already attracts the class that it ought to repel, and repels the class that it might benefit. One would imagine that the Poor Law is deterrent enough already without making it still more deterrent to decent poor women. But perhaps it is thought that it will help the crusade against workhouses.

THE DARWIN CENTENARY AT CAMBRIDGE.

The centenary of the birth of Charles Darwin has been celebrated this week with much ceremony at Cambridge. Darwin was born on February 12th, 1809, and an article on his early career and his relation to medicine appeared in the *JOURNAL* of February 13th; we need not dwell further on the subject here. Two hundred and thirty-five universities, 167 of which are foreign or colonial, sent delegates to do honour to the memory of one of Cambridge's greatest sons.

Medical Delegates.

Among the delegates were many members of the medical profession. Among the representatives of British medical bodies were the President of the Royal College of Surgeons of England; Dr. A. J. Horne, President of the Royal College of Physicians of Ireland; Dr. W. A. Jamieson, President of the Royal College of Physicians of Edinburgh. The Royal College of Physicians of London was represented by Dr. Norman Moore. Among the delegates of the University of Oxford was Professor Gatch. The University of Edinburgh was represented by its Principal, Sir William Turner; that of Glasgow by its Principal, Sir Donald MacAlister; that of Aberdeen by Professor Trail, M.D. Among the French delegates were Professor Le Dantec, of Paris, and Dr. Metchnikoff, of the Pasteur Institute; among the German were Professor Waldeyer, of Berlin. Professor Max Verworn, of Goettingen. The University of Melbourne was represented by Dr. C. J. Martin, Director of the Lister Institute; the University of Toronto by Professor T. G. Brodie.

Publications.

Some interesting literature has appeared in connexion with the Centenary. The *Order of the Proceedings at the Darwin Celebration held at Cambridge, June 22-June 24, 1909*, printed at the Cambridge University Press, contains a fine photograph of the author of *The Origin of the Species*, as he was in 1881, and another photograph taken in 1849. There is an interesting sketch of his life, with photographs of persons and places connected with him, such as John Stevens Henslow, who may be said to have launched him on his career as a naturalist, Sir Joseph Dalton Hooker, Mrs. Darwin, Darwin's birthplace at Shrewsbury, his rooms in Christ's College, his house at Down in Kent, and H.M.S. *Beagle*, in which he made his memorable voyage.

The *Christ's College Magazine* has issued a Darwin Centenary Number, which contains a large amount of interesting matter about Darwin's Shrewsbury days; Darwin at Cambridge and at Edinburgh; Christ's College in the days preceding his entry; letters from him to A. R. Wallace; and a list of plants named after him.

A publication of special interest is *The Foundations of the Origin of Species*, a sketch written in 1842, and edited by his son, Mr. Francis Darwin, who contributed an introduction in which the evolution of his father's thought is traced. It is printed at the Cambridge University Press.

Address of the President of the Royal College of Surgeons of England.

The following address was presented by Mr. HENRY MORRIS, in the name of the Royal College of Surgeons of England, of which he is President. We are happy to be able to print it in full, as it is particularly interesting to members of the medical profession:

The Council, Fellows, and Members of the Royal College of Surgeons of England experience in a very special degree a deep sense of gratification in having been honoured by an invitation to send a delegate to the Commemoration by your university of the centenary of Charles Darwin's birth and the fiftieth anniversary of the publication of his great epoch-making work *On the Origin of Species by Means of Natural Selection, or the Preservation of Favoured Races in the Struggle for Life*.

We feel a peculiar, indeed an almost personal and certainly a professional, pride in taking part with your great commonwealth of learning and knowledge as a whole, and with Christ's College, and the Faculty of Natural Sciences in particular, in this In Memoriam celebration of one who in so conspicuous and brilliant a manner added lustre to this great and ancient university.

The numerous, and intimate personal, and family associations of Charles Darwin with the University of

Cambridge are equalled by similar connexions with the profession of medicine. We are mindful that his grandfather, the celebrated scientist and poet, Dr. Erasmus Darwin, was a physician at Litchfield, and afterwards at Derby; that his father was a very successful medical practitioner at Shrewsbury; that his only brother was a Bachelor of Medicine of Cambridge, and that his paternal uncle and he himself were intended for the medical profession, and actually studied physic at the University of Edinburgh.

The sciences to which Charles Darwin devoted his life and on which he built his great generalizations are, some of them, ancillary to medicine, and, as developed and interpreted by him, they transfigured many of the doctrines and classification of disease, illumined with new conceptions pathology as well as biology, and opened up fresh avenues of thought, and new pathways of investigation, leading to a more correct and scientific knowledge and practice of the resources of surgery.

To the museum of our college Charles Darwin presented about thirty valuable specimens of fossil mammalia collected by him during the voyage of the *Beagle*, a fact which may not be generally known.

To the students of medicine as well as to the students of general biology Darwin has left on record a caution of the utmost importance, and at no period more than at the present time have they had greater need to be reminded of it. He tells in his autobiographical recollections how his neglect of dissecting when a student in Edinburgh "proved one of the greatest evils of his life"; how the anatomical knowledge and aptitude he would have gained by the practice of dissection would have been invaluable for all his future work; and how the want of these and his incapacity to draw had been an "irremediable evil," and that "a great pile of manuscript" which he had made during the voyage of the *Beagle* had in consequence "proved almost useless."

Charles Darwin esteemed it a high honour to have been elected an honorary member of the Royal Medical Society of Edinburgh, and an original honorary member of the Physiological Society which was founded in London in 1876. By his efforts to forward legislation on the question of vivisection, by his private communications to physiologists and others, and by his letters to the editor of the *Times* "on the right of experimenting on living animals" he showed the righteousness as well as the wisdom of his judgement by denouncing the practice of vivisection for "mere damnable and detestable curiosity," whilst he endeavoured to obtain "justice to science," and gave proof of his willingness to bear his "share of the abuse poured in so atrocious a manner on all physiologists." Though, in his own words, "Hippocrates had taken the wind out of my sails," though when informed of the views on pangenesis of this philosopher of antiquity Charles Darwin admitted they seemed almost identical with his own, and although theories somewhat akin to those of the *Origin of Species* had been advanced by Buffon, Lamarck, and Erasmus Darwin, and the principle of natural selection had been enunciated by Dr. Wells and Mr. Matthews, yet the central hypothesis of the *Origin of Species* came in 1859 as a revelation to the historians of scientific ideas as well as to all the biological specialists then living. Charles Darwin knew that he was regarded as "the greatest revolutionist in natural history of that if not of all centuries," and he naturally yearned for some half-dozen great and sound scientists to accept his views, for then he would have no fear of their ultimate success.

And whose were the opinions he most especially valued and "longed to learn"? They were those of J. D. Hooker, Charles Lyell, Huxley, Richard Owen, W. B. Carpenter, Milne-Edwards, and Asa Gray, every one of whom, except Sir Charles Lyell, had received a medical education, and was the holder of a medical degree, or other medical qualification. Two of them, Huxley and Owen, had been intimately associated with the Royal College of Surgeons of England—Huxley as a member of the college and Hunterian Professor, and Owen as a member and Fellow of the college and Hunterian Professor and Conservator of the Hunterian Museum for many years. Hooper and Huxley were the most sympathetic exponents and staunchest champions of the Darwinian principles, and if Owen never actually expressed a definite opinion of Darwinism, he at least inclined to the theory of "natural

selection," and conduced to the writing of a letter in which Charles Darwin evinced a candour, a modesty, a tolerance of disagreement, and an indifference to the claims of priority which so supremely characterized him throughout his whole scientific career.

It is interesting to us who are connected with the College of Surgeons to recall that in 1859 Owen delivered the Rede lecture at Cambridge—his subject being the classification of mammalia—and that he then received the degree LL.D., thus becoming the recipient of the first honorary degree ever conferred by this university. Also, in the same year, the remains of John Hunter, the great founder of scientific surgery, the fruits of whose labours will for all time be the chief glory of our college, were removed from the vaults of St. Martin's-in-the-Fields to Westminster Abbey. If, instead of the reinterment of the body—lifeless for sixty-six years—Hunter could have been restored to life in this world, it is only reasonable to conclude, from the opinions expressed in several of his writings, that he would have greeted the *Origin of Species* with great delight, and would have given it the readiest and fullest acceptance.

For these, amongst other more general reasons, does our college, with special zest and gladness, beg to offer to the university our best wishes for the success of these memorial ceremonies, and to thank her for affording us the pleasure and satisfaction of joining with the representatives of the liberal arts and sciences from all parts of the world in this tribute of honour to the name and fame of one of her most illustrious sons.

THE

THERAPEUTIC APPLICATIONS OF RADIUM: METHODS AND RESULTS.

TREATMENT OF INOPERABLE CANCERS BY RADIUM.

Our Paris Correspondent writes that at the last meeting of the Académie de Médecine Dr. Dominici made a communication on the results he had obtained in the treatment of deep-seated inoperable cancers by radium, used in a hollow apparatus containing the pure radium salt, the radiations from which were filtered through a sheath of a dense metal such as gold or silver. This apparatus was inserted into the mass of the cancerous tissues. Dr. Dominici reported the following results:

1. The disappearance of a malignant tumour of the parotid, a lymphadenoma treated in the wards of Dr. Bazy, by the introduction into the substance of the tumour of an apparatus containing 5 mg. of pure radium bromide enclosed in a gold cylinder, the wall of which was $\frac{1}{16}$ mm. thick. The apparent cure had lasted for six months.

2. The amelioration of an inoperable sarcoma of the neck, treated in the wards of Dr. Regnier by the introduction into the mass of the tumour of a silver apparatus $\frac{1}{16}$ mm. thick, the cavity of which contained 5 cg. of pure radium bromide. The sarcoma had decreased in volume and become mobile enough to allow M. Chiffoleau, assistant to Dr. Regnier, to remove the tumour surgically, which had till then been impossible.

3. The disappearance of a cancer of the parotid (epithelioma) treated by the same method in the wards of Dr. Schwartz.

Other malignant tumours, of different kinds and in various situations, treated in the wards of Drs. Segond, Tuffier, and Piqué, had been ameliorated. Dr. Dominici did not consider as definitely cured even those tumours which had disappeared for several months, for metastasis might have occurred and the fear of recurrence was still present; but the observations showed that (1) inoperable tumours had been rendered operable, and that (2) general disorders and the local lesions of patients with tumours in the presence of which the surgeon was powerless had been suppressed or greatly attenuated.

THE twenty-ninth annual meeting of the Ontario Medical Association was held in Toronto on June 1st, 2nd, and 3rd. There was a large attendance, and a number of valuable papers were read, among others one by Dr. Deaver, of Philadelphia, on Diffuse Peritonitis, which aroused a good deal of discussion, the point in dispute being the advisability of the author's method of mapping the infected peritoneum. Dr. L. Emmett Holt read a paper on Results of the Serum Treatment of Cerebro-spinal Meningitis, with report of some 700 cases. Dr. Osler gave the address on Medicine; a Philosophical Study of the Practice of Medicine.

BRITISH MEDICAL BENEVOLENT FUND.

At the June meeting of the committee fifteen cases were considered and grants amounting to £129 made to twelve of the applicants, two cases being passed over and one postponed for further inquiry. Dr. F. G. Crookshank was appointed honorary local secretary at Barnes and Dr. C. E. Solomon an additional local secretary at Liverpool. Appended is an abstract of the cases relieved:

1. M.R.C.S., L.R.C.P., aged 38. Has had a small country practice, but for the last eight months has been incapacitated by general paralysis of the insane, and is now confined in an asylum. Small savings have been quite exhausted by providing a locum tenens and by unavoidable expenses of the illness, and so far it has not been possible to sell the practice. Two children, the younger only a few months old. Voted £10 to the wife.

2. Daughter, aged 53, of late M.R.C.S., L.S.A. No income; health too indifferent to undertake laborious or continuous work, but obtains a light post as companion when able to do so. Relieved three times, £30. Voted £10.

3. Daughter, aged 58, of late L.S.A. No income; has supported herself as housekeeper or companion for the last fourteen years, but is now incapacitated by locomotor ataxia. Voted £12.

4. Widow, aged 63, of M.D. Edin. Quite unprovided for at husband's death eighteen months ago, and endeavours to make a living by letting lodgings. Is allowed a few shillings a week by some distant relations. Voted £6.

5. Widow, aged 90, of F.R.C.S. Since husband's death has been living on the proceeds of the sale of furniture, and now receives an old age pension. No children; is quite blind. Voted £18.

6. Daughter, aged 52, of late L.R.C.P. Edin., L.S.A. Unable to earn a living on account of heart disease and defective eyesight, and is dependent on two sisters, who have to support themselves, and can ill afford to help. Relieved four times, £36. Voted £10.

7. Daughter, aged 60, of late M.R.C.S., L.S.A. Has a pension of £14 a year from the Admiralty and receives a little help from Lloyd's Patriotic Fund. Relieved twelve times, £70. Voted £5.

8. Daughter, aged 62, of late M.R.C.S., L.S.A. No income, and being mentally deficient, is dependent on a relation who can only help with difficulty. Relieved three times, £36. Voted £12.

9. Widow, aged 62, of L.R.C.P., L.R.C.S. Edin. Since being left a widow, nearly fifteen years ago, has supported herself by taking lodgers, but finds the necessary work increasingly difficult. Two children, one just self-supporting, the other still at school. Relieved twice, £24. Voted £12.

10. Widow, aged 31, of L.S.A. No income; endeavours to maintain herself by nursing, but has been incapacitated during the last three months by acute rheumatism, and is told that a rest is absolutely essential before taking further cases. Three children, 10 to 3. Relieved twice, £15. Voted £10.

11. Widow, aged 58, of L.R.C.P., L.R.C.S. Irel. Since husband's death has endeavoured to support herself by maternity nursing, but is now nearly blind. Relieved fifteen times, £137. No children. Voted £12.

12. Widow, aged 59, of M.D. St. Andrews. No income; slight occasional help from children. Lets lodgings, but has been obliged to part with some of her furniture to make both ends meet. Relieved five times, £60. Voted £12.

Contributions may be sent to the Honorary Treasurer, Dr. Samuel West, 15, Wimpole Street, London, W.

LITERARY NOTES.

We are informed by Professor Dr. Pilcz, of Vienna, that the official general report of the Third International Congress on the Nursing of the Insane will be published in July. A copy will be sent to each member of the Congress. Non-members may obtain the report from C. Marhold, Halle.

The first number of a new medical journal entitled *Heart*, dealing exclusively with the circulatory system, will be issued early in July. The aim of the journal is to further the progress of knowledge of the mechanism by which the blood circulates in health and disease. The editor is Dr. Thomas Lewis, who will be aided in the selection of papers by Dr. W. H. Gaskell, Professor A. R. Cushny, Dr. J. Mackenzie, Professor A. W. Hewlett (Ann Arbor), and Professor G. N. Stewart (Cleveland). Among the collaborators are Sir T. Clifford Allbutt, Professor Rose Bradford, Sir Lauder Brunton, Dr. G. A. Gibson, Professor F. Gotch, Dr. T. W. Griffith, Dr. W. P. Herringham, Professor A. Keith, Professor J. A. MacWilliam, Dr. S. J. Meltzer (New York), Professor Joseph L. Miller (Chicago), Sir Richard Douglas Powell, Professor E. H. Starling, Professor Graham Steel, and Professor G. S. Woodhead. The first number will contain a preface by Dr. W. H. Gaskell, an editorial preface, and the following papers:

Professor A. R. Cushny, on the irregularities of the mammalian heart observed under acotinine and on electrical stimulation; Dr. James Mackenzie, on nodal bradycardia; Dr. Thomas Lewis, on paroxysmal tachycardia; and Dr. Leonard Hill, on the measurement of systolic blood-pressure in man. The journal will be issued, as far as possible, at regular quarterly intervals, and each volume will consist of four numbers. The publishers are Messrs. Shaw and Sons, Fetter Lane, Fleet Street, London, E.C.

On June 13th the Frankfort Medical Association celebrated the centenary of the birth of Dr. Heinrich Hoffmann. Dr. Hoffmann was Medical Director of the Frankfort Lunatic Asylum, and during the fifty years of his connexion with that institution he made it so widely known that sufficient funds were collected to rebuild it at a cost of 600,000 gulden. Distinguished as was his medical work, Dr. Hoffmann was probably still better known as the author of the famous nursery book, *Struwwelpeter*. He also wrote a large number of epigrams, satirical or humorous sketches, and poems on a variety of subjects.

In the current number of the *Cornhill Magazine* Canon John Vaughan gives an interesting account of a forgotten botanist of the seventeenth century. He says that when Dr. William Tanner, Dean of Wells, in the reigns of Edward VI and of Queen Elizabeth, published his black-letter *Herbal* only some 300 British species of plants were enumerated. A century later the number of plants in Ray's *Catalogue* had risen to 1,050; and when in 1696 the second edition of his "Synopsis" was published fully 1,600 species are described. In many instances the names of those who by their discoveries had thus helped to enrich our knowledge of British plants are duly remembered. The labours of such men as Lobel, Gerard, Johnson, Parkinson are abundantly evident in their writings. In some cases the finder's name has been bestowed upon the plant itself, and in this way the services of Sherard, Sibthorp, Teesdale, and others have been commemorated. In many instances, however, the honour due to our early herbalists has been but scantily recognized, and the names of several who rendered distinguished service to the science in its early days have passed into almost total oblivion. Amongst these we would venture, as a conspicuous example, to place the name of Mr. John Goodyer, of Maple Durham, in Hampshire. His services are repeatedly acknowledged in contemporary botanical literature; by virtue of the large number of rare plants which he discovered he should, undoubtedly, be placed at the head of our Hampshire botanists, and yet his name is passed over in silence in the *Dictionary of National Biography*, and the very identity of his place of residence has been called in question. Parkinson writes a few years later, speaking of him in his *Theatrum Botanicum*, published in 1640, as "a great lover and curious searcher of plants, who hath found in our country many plants not imagined to grow in our land." He is mentioned by Dr. How in his *Phytologia*, and Merret, in his *Pinax*, speaks of him as "an incomparable botanist, of sound judgement and of immense industry." Ray frequently acknowledges his services both in the "Synopsis" and in the "List of Rare Plants," which he supplied to Gibson's edition of Camden's *Britannia*. And Pulteney, in his Botanical "Sketches," published in 1790, thus sums up the very brief notice of his work:

The great number of rare English plants which Mr. Goodyer brought to light entitles him to the most reputable rank among those who have advanced the botanical knowledge of the kingdom.

At Maple Durham, then, either in the larger or the smaller house, Mr. John Goodyer lived during the first half of the seventeenth century. There he had a fine garden, or, rather, "gardens and orchards," in which he cultivated rare and curious plants. We find him supplying the famous Mr. Parkinson with the seeds of wild lettuce, the juice of which plant, he says, hath "a very strong and grievous smell of opium." He doubtless visited the different Physic Gardens, at that time beginning to spring up in various parts of the country, such as those at Oxford and Holborn, the one, it may be, in company with Mr. William Brown, Fellow of Magdalen, and the other with old John Gerard himself, who cultivated, we are told, "near eleven hundred sorts of plants." He seems to have been the first to describe the male fern, which he found "growing abundantly on the shadowy moist rocks by

Maple-Durham neere Petersfield, July 4th, 1633." He was also the first to discover the Narrow-leaved Lungwort, or "Long-leaved Sage of Jerusalem" (*Pulmonaria angustifolia*, L.) to be a British plant. He found it "May 25, anno 1620, flowering in a wood by Holbury house in the New Forest." This is one of our most interesting Hampshire plants, not only because it is confined almost entirely to the New Forest and the Isle of Wight, but also on account of the use made of it by the old herbalists in cases of pulmonary diseases. Another plant of famous medicinal virtue, which Goodyer found plentifully "in the unmanured inclosures of Hampshire and on chalky downes," was the Purgive or Cathartic Flax, which he calls "Mill-mountain." His account of how he came to know the name and properties of this plant is so quaint as to be worth quoting in full:

On the second of October 1617, going to Mr. Colsons shop an Apothecarie of Winchester, I saw this herbe lying on his stall, which I had scene growing long before; I desired of him to know the name of it; he told mee that it was called Mill-mountaine; and hee also told me, That being at Doctour Lake his house at Saint Crosse a mile from Winchester, seeing a man of his have this herb in his hand, he desired the name; hee told him as before, and also the use of it which is this: Take a hand full of Mill-mountaine, the whole plant, leaves, seeds, floures and all, hew it in a small tune or pipkin of a plate filled with White Wine, and set it on the embers to infuse all night, and drinke that Wine in the morning fasting. This Dr. Lake was afterwards made Bishop of Bath and Wells, who always used this herbe as his physic, after the said manner, as his man affirmed.

The medicinal qualities of plants had a great fascination for our friend Mr. Goodyer, as indeed they had for all early botanists. He is ever on the look-out for information as to the virtues of herbs, and he sometimes meets with it in unexpected quarters. The corn-parsley he had for years observed in the clay grounds around his home, but it was not till the year 1625 that he realized what a wonderful virtue it possessed. This is the story:

I saw Mistris Ursula Leigh (then servant to Mistris Bilsom at Maple-durham, and now (5 Martii 1632) wife to Mr. William Mooring, Schoolemaster of Petersfield, a Towne near the said Maple Durham) gather it in the wheate ershes about Maple Durham aforesaid, who told mee it was called Hone-wort, and that her Mother Mistris Charitie Leigh, late of Brading in the Isle of Wight, deceased, taught her to use it after the manner here expressed, for a swelling which she had in her left cheeke, which for many yeares would once a yeare at the least arise there, and swell with great heate, rednesse and itching, until by the use of this herbe it was perfectly cured and rose no more nor swelled, being now (5 Martij 1632) about twenty-three yeares since, only the fear remaineth to this day. This swelling her mother called by the name of a Hone, but asking whether such tumours were in the said Isle usually called Hones she could not tell, by reason she was brought from Brading aforesaid young, and not being above twelve yeares old when she used the medicine.

Mr. Goodyer then describes how, instructed by Mistris Leigh, the parsley should be used:

Take one handfull of the greene leaves of the Hone-wort, and stamp them, put to it about halfe a pint or more of beer, straine it, and drinke it, and so continue to drinke the like quantity every morning fasting, till the swelling doth abate, which with of in her was performed in the space of two weeks at the most.

John Goodyer died in the spring of 1664, and was buried, as he directed in his will, in "the churchyard of Buriton, near his late wife."

In connexion with the cheerless weather of this summer it is interesting to find that a similar condition of affairs existed in London exactly one hundred years ago. The Quarterly Report of Diseases treated at the Public Dispensary, near Carey Street, London, from May 31st to August 31st, 1809, has appended to its list of the names and numbers of the prevailing maladies the following paragraphs: "The summer months have been unusually wet and cool. A few warm days occurred in the third week of June, in the second week of July, and about the end of August; but the remaining portions of those months were cool, often very chill, with almost daily rains, accompanied with thunder and lightning." *Abit omen!* "On the whole, however," the report continues, "a damp and cool summer is favourable to the health of the inhabitants of London, and accordingly the number of applicants to the dispensary has been smaller than is usual at the summer season." This reflection must have seemed cold comfort to the Londoners of a hundred years ago, who doubtless were willing to suffer a little in order to have fine weather.

Medical News.

THE first Greek Congress on Tuberculosis has recently been held under the patronage of the Crown Prince of Greece.

IN accordance with the policy settled last year, the London Education Committee intends shortly to appoint twenty-six additional assistant school medical officers.

THE Lord Chancellor has added the name of Dr. T. W. Clay, of Holyhead, to the Commission of the Peace for the county of Anglesey, on the recommendation of Sir Richard Williams Bulkeley, Bart., Lord-Lieutenant for the county.

AT a Chapter-General of the Order of the Hospital of St. John of Jerusalem in England on May 25th, Major J. Robertson Reid, M.D., R.A.M.C.(T.), Birkdale, was selected an Honorary Associate, in recognition of services rendered in connexion with ambulance work.

THE annual exhibition at University College of Egyptian antiquities found by Professor Flinders Petrie and students at Memphis (Palace of Apsies) and Thebes will be open from 10 till 5 from July 5 to July 31st, and on the evenings of July 5th and July 15th from 7 till 9.

THE annual luncheon of the Continental Anglo-American Medical Society will be held on Thursday, July 29th, at Belfast, during the annual meeting of the British Medical Association. Members intending to be present should communicate with Dr. C. G. Jarvis, the Hon. Secretary, 81, Boulevard Malesherbes, Paris.

A COURSE of twelve lectures on tuberculosis of the bones and joints will be given at the Maritime Hospital, Berck-sur-Mer, Pas-de-Calais, near Boulogne, by Dr. Menard, chief surgeon, and Drs. Andrien and Calvé, assistant surgeons. The lectures, which will be illustrated by cases, specimens, and casts, will be delivered from August 2nd to August 13th. The fee for the course is Fr.50. Further information as to hotels, etc., can be obtained from the Agence Lafillé et Gerardin, Berck-sur-Mer.

A SERIES of post-graduate lectures will be given at the London School of Dental Surgery connected with the Royal Dental Hospital, Leicester Square, during October and November. The lectures will deal with pathogenic organisms of the mouth, periodontal disease, stagnation and drainage, vaccine treatment, radiographs, and pathological conditions of the third molar. Past and present students of the hospital and internal students of the University of London will be admitted free; the fee to others will be 2 guineas. Further particulars can be obtained on application to the Dean.

THE twelfth annual dinner of the West London Hospital and Post-Graduate College took place at the Trocadero on June 16th, the company numbering over 150 persons. Dr. Phineas Abraham presided, and the guests included Surgeon-General A. M. Branfoot, I.M.S., and Fleet Surgeon C. E. Stalkart, who replied to the toast to the Imperial Forces; Sir Havelock Charles and Dr. C. O. Hawthorne, who responded to the toast to "The Guests and Kindred Colleges." In the course of the evening it was mentioned by Mr. Bidwell that the entry of post-graduate students last year reached a total of 232, and that since the establishment of the college in 1896, over 1,700 medical men, largely consisting of officers of the Royal Navy and the Indian Medical Service, had enjoyed its benefits.

THE West Kent Medico-Chirurgical Society, now in the fifty-fourth year of its existence, gave its annual dinner on June 18th. The president of the society, Mr. Septimus Barnett of Lewisham, was in the chair, and the company included a very large number of guests. Among the latter was the Rev. E. Grundy, who drew an analogy between sacerdotal and medical general practitioners which was interesting and humorous in its completeness. The difficulties with which they had to contend and the pitfalls which awaited them were of a corresponding kind; they gained an equally wide acquaintance with the best and the worst sides of human nature, and the qualities which were required to make a successful general practitioner served also to promote the success of the parish priest. In the course of the evening the view was expressed that the time had come when, for its own protection and for the eventual benefit of the public, the medical profession should enter into close defensive union. As an instance of the arbitrary fashion in which its individual members are liable to be treated, a mandate recently issued by the Postmaster-General was quoted. It renders a postal medical officer liable to have thrust upon him at any time the care of a patient whom he has not contracted to attend, but whom, nevertheless, he is practically obliged to treat at a rate which in many instances may work out at an absolute loss.

THE late Dr. Hall, of St John's Wood, and formerly of Crouch End Hill, left estate of the net value of £87,679. We are informed that Dr. Hall was unmarried, and that a wealthy patient left him a large sum of money. Dr. Hall, who was a graduate of the University of Glasgow, after legacies to a number of charities, including Epsom College, the British Medical Benevolent Fund, the National Hospital for the Paralyzed and Epileptic, Queen Square, and the Royal London Ophthalmic Hospital, and one of £1,000 to the Research Defence Society, bequeathed the balance to the University of Glasgow for the foundation of tutorial fellowships. An account of these is given elsewhere.

THE annual meeting of the Poor Law Medical Officers' Association will take place on Tuesday, July 6th, at the Guildhall, London, when a conference of the Poor Law medical officers of England and Wales, to consider the recommendations of the Royal Commission on Poor Law Medical Relief, which will be opened by the Right Hon. the Lord Mayor in the Council Chamber, at 11 a.m. Papers will be read on district medical officers and the report of the Royal Commission, by Dr. Major Greenwood, D.P.H., LL.B.; on medical relief and public assistance, by Mr. C. S. Loch, Secretary of the London Charity Organization Society; on the place of the district medical officer in a unified county medical service, by Mrs. Sidney Webb; on the genesis of the Poor Law infirmary, by Dr. F. S. Toogood, Medical Superintendent, Lewisham Infirmary; and on the public health aspect of the report of the Royal Commission, by Dr. G. F. McCleary, M.O.H., Hampstead. The papers will be followed by discussions, and the special business of the association will be conducted at 2 p.m., after which any matters postponed from the morning will be continued. The annual dinner will be held at the Waldorf Hotel, Aldwych, London, at 7.30 p.m. the same evening, Surgeon-General Evatt, C.B., the President of the Association, being in the chair. The price of the tickets is 7s. 6d., not including wine. Any Poor Law medical officer wishing to be present is requested to communicate with the Honorary Secretary, Dr. Major Greenwood, 243, Hackney Road, N.E. Ladies are admissible among the guests. The Lord Mayor and Lady Mayoress have kindly invited Poor Law medical officers attending the conference to afternoon tea at the Mansion House between 3.30 and 6 p.m.; the invitation includes ladies.

AT the last meeting of the Socialist Medical League, Dr. Salter, L.C.C., chairman, said that the medical profession, along with every section of society, was moving in the direction of collectivism; the special knowledge and training of the medical profession could be enlisted to shape the movement on scientific lines. In Japan the manufacture and supply of drugs for medical purposes had been undertaken by the State, and a Government Commission was sitting at the present time in Tokio to discuss the advisability of the medical profession being nationalized. The main factor had been the extraordinary anomaly that while the fever raged the doctor flourished, but when the country had a clean bill of health the doctor starved. Dr. Robb of Bourneville said that the private practitioner was between the upper and nether millstones of the club and the dispensary and hospital. He was not paid to prevent disease. Whilst preventive medicine under State control had markedly advanced, it was only by a complete development of the national system that the ideal could be attained. By the nationalization of the medical profession hospital abuse would cease. State insurance would include medical aid, for only thus could the national funds be adequately protected both from the effects of disease and from the wiles of the malingerer. Dr. McVail in his report to the Royal Commission on the Poor Law had maintained that free access to and the acceptance of medical advice on the part of the general community would result in great improvement in the average physical health and great diminution in the prevalence of disease. Dr. Burton said that nationalization would be brought about not by medical men, but by the people through an economic revolution. Dr. Rose said that the teacher of the future would be the medical man. Nine millions a year were being spent in providing for old people who were of no use to the State, yet there was hesitation to spend even one million on the children, who were the chief assets of the country. Surgeon-General Evatt said that every army medical officer was a sanitary officer, and better treatment had produced better men. If every medical man in the country was a sanitary officer, paid to prevent disease, the slums and all their attendant evils would be got rid of. The discussion was continued by Drs. Clarke, Bruce, Appel, and others.

SATURDAY, JUNE 26TH, 1909.

PNEUMOCOCCUS INVASION OF THE THROAT.

MEDICAL science can point with justifiable pride to the almost complete extinction of some diseases, notably typhus, and to the great diminution in the prevalence of others, such as small-pox, tuberculosis, and typhoid fever, which are among the results achieved by it during the last half-century. But, like the voice behind the hero of a Roman triumph telling him that he was mortal, there is one disease that whispers a like chastening reminder in the ear of victorious hygiene. Professor Osler says that "among the maladies of modern life, pneumococcal infections alone have increased in frequency and severity." The pneumococcus, though it has not yet got the ill name among the public which it deserves, works an infinity of mischief in addition to the inflammation of the lungs with which its name is mainly associated. It is carried about from one part of the body to another by the blood and lymph channels. Not to speak of the pleura, it invades the heart, the meninges, the brain, the peritoneum, the joints, the kidney, the bones, and the ear, causing in these various parts secondary, and sometimes primary, inflammations. It has been found in the fetal blood and in the uterine sinuses in pregnant women suffering from pneumonia. It lurks in the throat, waiting for the opportunity offered by exposure to cold or other influence lessening the power of resistance. The wonder is that it should not oftener find a point of attack in the upper air passages. It is not improbable that it may be accountable for septic conditions of the throat which are attributed to more familiar agencies.

That the pneumococcus does sometimes find a weak spot in the throat, with the result that infective pharyngitis is produced, is shown by two remarkable papers published in the present issue of the JOURNAL. Some cases of pneumococcal pharyngitis were reported many years ago by French observers, references to whose papers will be found at the end of Dr. Elliott's paper, which appears at p. 1528. There also will be found a reference to a case recorded by Monro in the *Glasgow Medical Journal* of 1901. It was Sir Felix Semon, however, who, as far as we are aware, first dealt fully with the subject. His recognition of the importance of a previously almost unknown definite sequence of phenomena is equivalent to the discovery of a new disease. It is not to the man who first happens to notice a fact, but to him who, understanding its significance, calls attention to it and succeeds in getting it generally admitted, that the credit of a discovery properly belongs. In a lecture delivered at the Polyclinic in November, 1908, and published in the *Medical Magazine* for December of the same year, Sir Felix Semon reported two cases of affection of the throat characterized by a course entirely different from any known to him in other

diseases of that part. They showed, to use his own words, "the most curious oscillations between intensely painful inflammatory conditions of the throat and improvements which appeared to render complete and speedy recovery almost a certainty, but which repeatedly gave way to absolutely unexpected aggravations until finally—in the one case—certainly spontaneously, in the other during an iodide of potassium treatment—complete recovery took place." These cases, says Sir Felix Semon, were characterized by "profound asthenia, almost entirely afebrile course, and complete absence of swelling of the cervical lymphatic glands." In one case the pneumococcus was present almost in pure cultures, and in the other the cultures consisted mostly of pneumococcus; in both cases towards the end perforation of the palate occurred. The facts seemed to Sir Felix Semon to warrant a suspicion that the morbid process was of the nature of chronic sepsis due to invasion of the pneumococcus.

In the paper by him which we publish this week he records in detail another case, in which pneumococcus invasion of the throat was combined with tuberculosis. It is remarkable that while the pneumococcus attacked the pharynx, the tubercle bacillus at first confined its depredations to the larynx. Later the two parasites joined forces, as it were, and were found mingled together on the pharynx, the posterior part of the tongue, and the epiglottis. The case in some of its clinical features simulated tuberculosis, but the pneumococcal origin of the pharyngeal lesions was conclusively proved by bacteriological methods. The tuberculous infection supervened on the pneumococcal invasion.

Some other interesting cases of pneumococcus infection of the pharynx are reported at page 1528 by Dr. John Elliott, of Chester. These cases differed from those recorded by Sir Felix Semon in the suddenness of their onset and the acuteness of their course; the fever usually lasted no more than forty-eight hours. In one case there were auricular complications, which were also clearly traced to the action of the pneumococcus. It is noteworthy that pneumonia was very prevalent in the neighbourhood at the time, but there was no influenza. Although there was considerable swelling of the lymphatic glands under the jaw and the neck, the pharyngeal lesion was much less severe and ran a much shorter course than those in the cases reported by Sir Felix Semon.

With regard to the treatment, there is little to be said. In a paper published at p. 1530, Dr. Butler Harris discusses the therapeutic value of the pneumococcus vaccine in pneumonia. He brings forward evidence to show that successful inoculation for pneumonia is possible, and that in any case the treatment does no harm. He recommends that a vaccine from one or a number of virulent strains should be used, and that it should be introduced as early as possible. His conclusion is that infections of the lung by the pneumococcus which fail to resolve after an acute pneumonia, as well as pneumococcal infections of other areas, should be treated with a pneumococcal vaccine, and he believes that the treatment in such cases affords a reasonable prospect of success. It should be pointed out, however, that in two of Sir Felix Semon's cases the use of a pneumococcus vaccine proved useless; in one case the patient, himself a medical man, thought it did him harm. The number of cases is evidently much too small to form a solid foundation for any conclusion as to the value of the treatment. (Prof. Semon)

The papers open a new field of observation, but much spade work is still needed before definitive conclusions can be reached. Nevertheless, the thanks of the profession are due to the pioneers. The affections described by Sir Felix Semon and Dr. Elliott seem to have little in common beyond the presence of the pneumococcus. The severe form so vividly described by the distinguished laryngologist may not, as he himself suggests, be exceedingly rare; but we think it likely that the more acute affection described by Dr. Elliott is more frequent. We recommend our readers to study the papers for themselves and carefully to compare the clinical and pathological features of the affections there described and the differences in course and in the character of the lesions which they present. Now that attention has been so strongly called to the fact that the pneumococcus may invade the throat, practitioners will doubtless be on the watch, and will recognize it when it comes under their notice.

TOXAEMIC INFANTILISM.

CASES of intractable wasting and ill-development without obvious cause are frequent enough in infants. In older children cases in which there is a striking retardation in the growth of the body, implicating the skeleton, the muscles, and most of the organs, whilst there is a relatively fair development of the brain, are occasionally met with, but have received little attention. With the assistance of Dr. Emmett Holt, Professor Herter of Columbia University has studied five fully-developed and typical examples of this condition, and five others of shorter duration and subacute course. His observations were carried out for several years, and he has embodied his careful researches in a monograph of extreme interest and value.¹ It not only throws light on these cases of so-called "infantilism," but helps, perhaps, in the investigation of other conditions of ill-development in infants and older children.

Cases of infantilism usually first come under observation at ages varying from 4 to 6 years, and, according to Herter, the chief or essential features of the complaint are: An arrest in the development of the body; the maintenance of mental powers and fair development of the brain; marked abdominal distension; moderate degrees of anaemia; rapid onset of physical and mental fatigue; and various obtrusive irregularities referable to the intestinal tract. Of these signs the most striking is the arrest in development in regard to both bodily stature and weight. Thus, in one patient, at the age of 7 years the height was only 36 in. and the weight 25 lb. Another weighed only 29 lb. at the age of 9 years. Both weight and development may remain almost stationary for long periods of time, in spite of the utmost care to ensure dietetic conditions favourable to growth. In several instances it was noted that a slight tendency to increase of weight during the winter months was counterbalanced by a loss during the ensuing summer. These losses of weight were always attributable to intestinal disturbances—usually a moderate degree of diarrhoea. Any loss of weight incurred, too, was very slowly recovered from.

Of the other special features of infantilism, disturbance of the intestinal functions is the most striking

and characteristic. Diarrhoea was a prominent feature in all of Herter's cases. Pronounced watery diarrhoeal attacks, however, were comparatively rare. Much more frequently the intestinal disturbance was manifested by the appearance of soft stools containing an abundance of neutral fat, soap, and fatty acid crystals. In the absence of diarrhoea the stools are apt to be voluminous, light coloured, floating on water, sour-smelling in spite of the faecal odour due to the presence of indol and mingled with large masses of mucus. Herter carefully investigated both the bacterial flora and the chemical constituents of the stools. The most interesting result of the bacterial examinations was the discovery by Kendall of large colonies of Gram-positive organisms for which the name *Bacillus infantilis* is proposed. This organism, or rather type of organism, is, it would appear, normally present in the faeces of infants, whether suckled or hand-fed, but is ordinarily absent in the motions of children of older age. It is found associated with other Gram-positive organisms, the *Bacillus bifidus* of Tissier and the *Bacillus acidophilus* of Moro. For a detailed description of this *Bacillus infantilis*, with the means of its detection and cultivation, reference must be made to Herter's work. If further observations should confirm the author's conclusion that in the height and relapses of the complaint these Gram-positive micro-organisms almost entirely replace the *Bacillus coli* and the *Bacillus lactis aerogenes* in the faecal flora, the reverse being the case at stages of improvement, a clinical fact would be established that might prove of far-reaching interest and importance. The appearance and constituents of the stools have been sufficiently indicated for our purpose. It only remains to add that any undue increase of carbohydrates in the food leads to frothing, and increased frequency of the motions. An analysis of the amounts of calcium and magnesium in the food, and of those in the urine and faeces, showed that the output of these two salts was equal to the intake, with a remarkable degree of accuracy.

The urine was examined with the same care as the faeces. As a rule, the volume passed was excessive—800 c.cm. to 1,000 c.cm. in the course of the day. The most important features discovered on chemical analysis were a rise in the ethereal sulphates, the occurrence of an excess of phenol in the distillate, the presence of aromatic oxyacids, and a marked degree of indolaceturia in several cases. Each of these is held to be indicative of absorption of the products, and a putrefactive decomposition of the intestinal contents. Herter also found that the urinary evidence of intestinal putrefactive decomposition was greatest at the times when the Gram-positive organisms were the dominant ones in the faecal flora.

In the pathology of intestinal infantilism Herter considers that two leading features call for explanation—the retardation of growth and the chronic intoxication. According to him, "the retardation in growth can apparently be explained on the basis of the imperfect absorption of nutritive material, which can be demonstrated in these cases. This impaired absorption of foodstuffs is probably to be ascribed to a chronic inflammation located in the ileum and colon and associated with the presence of abnormal forms of bacteria. The intoxication, which is so prominent a feature of intestinal infantilism at its height, may confidently be ascribed to the action of putrefactive products of intestinal origin upon the central nervous system and

¹ On *Infantilism from Chronic Intestinal Infection*. By C. A. Herter. Professor of Pharmacology and Therapeutics, Columbia University. New York and London: The Macmillan Company. 1908. (Post 8vo, pp. 118. 4s.)

"muscles. The exact relation of the abnormal bacterial flora to the pathological conditions in the intestines is not yet clear. The chief evidence in favour of the causal relationship between the phenomena of infantilism and the overgrowth and persistence of flora of the nursing period, especially *B. bifidus*, is found in the changes that occur during convalescence when these organisms are replaced by those of the type appropriate to childhood. A further evidence in the same direction is seen in the great increase in the infantile types of bacteria during periods of relapse. There is no evidence at present that intestinal infantilism has any other origin than a purely intestinal one."

The prognosis in these cases is doubtful; many die from exhaustion, or from some intercurrent malady. Where the complaint has been of any severity, recovery is associated with permanent dwarfism, which may be very marked.

For such patients an equable temperate climate is desirable, as their body temperature is unstable, they readily lose heat, and any rapid changes of weather are likely to give rise to digestive disturbance. The main lines of treatment are, however, dietetic; a first essential being the reduction of carbohydrates and fats to digestible limits. When this has been attained, any increase of either of these two classes of substance should be made with extreme caution. As a proteid element in the food, Herter strongly advocates gelatine. As it contains neither a tryptophan nor tyrosin nucleus, he claims that its digestion in the intestine cannot give rise to indol, skatol, indolacetic acid, or any of the other substances responsible for the chronic intoxication in the child. Another reason for its administration is that the *B. bifidus* and the *B. infantilis* are practically uncultivable on gelatine media. It may well be, then, that gelatine may inhibit the growth of these organisms in the intestinal canal. The amount of gelatine recommended is 1 oz. in divided doses for a child of 7 or 8 in the course of twenty-four hours. In addition to other properties, it is claimed that this amount of gelatine would contribute 125 calories towards the maintenance of bodily temperature.

The recommendation of gelatine is of interest for other reasons: it was once held in high esteem in invalid cookery, but for many years past its nutritive value has been reckoned as little or nothing. At one time, again, it was a favourite addition to cow's milk for infantile use on account of its separating the particles of casein. Nowadays, however, it would appear to have been entirely superseded for this purpose by barley water and other substances. In the light of Herter's investigations it may be that gelatine had more valuable properties than that of merely separating the particles of casein when administered in milk to wasting babies, and that its supersession has been a mistake.

THE STATISTICS OF OPSONINS.

SINCE the introduction by Sir A. E. Wright of a method of testing the response of the body to infection and immunization by the fluctuations of the opsonic index numerous articles have appeared, in which the accuracy of the method as commonly employed has been called in question.

These protests have come from two quarters. The one party has urged that the technique of the method is subject to so high an error that reliable deductions

cannot be drawn from the indices—that, in fact, many of the minute variations recorded as significant by the whole-hearted opsonist come within the experimental error of the method. The other party (much the smaller number) contends that if the opsonic antibody is an amboceptor which co-operates with complement, the current method of estimating the amount of that antibody in a serum is not valid.

Until recently, however, no serious attempt had been made to test the validity of the opsonic method as at present practised by rigid mathematical analysis. This lacuna has now been filled by Drs. Greenwood and White in their recent contribution to *Biometrika*.¹ The authors set out from the consideration that the constants (mean, mode, etc.) cannot be deduced from a certain distribution unless the form and extent of that distribution be known. In the opsonic technique a varying number of leucocytes containing a varying number of micro-organisms are observed and recorded, and an average value is deduced by dividing the total number of micro-organisms taken up by the total number of leucocytes counted. In comparing one serum with another, therefore, the means are taken as the most probable values resulting from the distributions. Obviously the mean would be appropriate only if the distribution followed the normal or Gaussian curve of error (a symmetrical curve). Greenwood and White, therefore, in this first memoir proceed to determine the nature of the frequency curve formed by plotting the number of micro-organisms per cell against the frequency of that cell. A few preliminary analyses were made with material obtained at the London Hospital. A series of counts of 75 cells was compared with control counts made on the same day, and with the same emulsion. The difference between the mean of each count and that of the control was estimated along with its probable error on the assumption that the distributions followed the normal or Gaussian curve. Taking the usual statistical criterion for significance they found that values below 0.8 and above 1.2 were certainly significant, but the figures when plotted out or even casually examined showed a markedly skew arrangement, thus foreshadowing the results of their analysis of a far more extensive mass of material. This latter was prepared by the best technique available, and was placed at the disposal of the authors by Dr. Strangeways of Cambridge and Dr. Fleming of St. Mary's Hospital. Dr. Strangeways supplied eight sets of 1,000-cell counts and one count of 2,000 cells, while Dr. Fleming supplied six counts, the number of cells in each varying from 400 to 1,100. Each of these distributions was now analysed, and the mathematical criteria necessary for the application of one or other of Pearson's frequency curves worked out. It may be mentioned that these curves introduced into statistical work by Professor Karl Pearson are of a very general type, and include the normal or Gaussian curve of error merely as a particular case.

The arithmetical labour entailed in an investigation of this kind is enormous. Suffice it to say that the authors have worked out the equations of the curves which fit most closely all the various distributions.

These curves are without exception of markedly skew type, rising fairly rapidly to a maximum point, passing through a point of inflexion and then declining very gradually to the base line. Pearson's Type I can be

¹ A Biometric Study of Phagocytosis, with Special Reference to the Opsonic Index. First memoir: On the frequency distributions of phagocytic counts. *Biometrika*, Vol. vi, No. 4, March, 1909.

fitted to ten of the curves, while the remaining four are satisfied more closely by Type V. To none of the distributions can the normal or symmetrical curve of error (in which the mean coincides with the mode and divides the curve into two exactly similar parts) be fitted. The skewness was markedly less in Fleming's curves than in those of Strangeways, and the question arose whether this reduction in skewness could be accounted for by the somewhat thicker emulsions with which Dr. Fleming purposely worked, and the correspondingly higher values which he obtained for the modes. Though this circumstance would partly account for the reduced skewness, the authors conclude from the result of a rather intricate method of analysis, which cannot be illustrated here, that Strangeways's counts were more truly random samples of the whole population of leucocytes than those of Fleming, and consequently afforded a more reliable guide to the whole distribution.

The main conclusion which arises from this elaborate paper is, that the normal curve of error does not apply to phagocytic distributions, and consequently that the mode (that is, the number associated with the greatest frequency of cell) would be a more reliable measure of the whole distribution than the mean. The authors reserve for a further memoir the analysis of the frequency curve formed by the means of equal samples taken from a large population of leucocytes. Naturally for adequate statistical treatment of this question a large number of cells would be required (perhaps 15,000), but the authors have performed a preliminary analysis with a count of 2,000 cells made by Dr. Strangeways, who grouped his results in 80 batches of 25. The curve of means (of 25 cells), though admittedly based on a paucity of data, was also found to be of skew type (Pearson's Type I), and accordingly the calculation of probable errors on the basis of the normal curve of error would be quite inappropriate.

We cannot too strongly praise the valuable statistical investigations which Dr. Greenwood and Dr. White have carried out on what might be called the quantitative side of immunity work. It marks a distinct forward step, and similar methods might with advantage be employed in other questions affecting immunity. To the critic who asserts that opsonic data are not suitable for such statistical treatment there can be but one reply—namely, that the best technical skill has been employed in the preparation of the material used by the authors in their work. Of the validity of their analyses from a purely mathematical point of view there can be no question. They have shown that phagocytic distributions resulting from the ordinary opsonic technique are markedly skew. This is certainly a result of immense importance, but one would wish to know whether the form of the phagocytic distribution is entirely independent of the method by which the amount of opsonic antibody in a serum is estimated. One point, for instance, which we hope the authors will attempt to investigate, is the estimation of the probable effect on the frequency curve of other methods of testing quantitatively the amount of opsonin. The employment of heated serum, or inactivated and complemented immune serums, might conceivably lead to some modification in the amount of skewness of the frequency curves.

In the meantime, the authors are heartily to be congratulated on the result of their work, and their future contributions to the statistical side of the opsonic question will be awaited with interest.

DEATH OF PROFESSOR D. J. CUNNINGHAM.

WE have to announce with the most profound regret, a regret which will be shared by countless friends and old pupils all over the world, the death on Wednesday last, June 23rd, of Professor D. J. Cunningham, of Edinburgh. Some months ago he went to Egypt in the hope that a change to that kindly climate, along with absolute rest, would bring about a renewed vigour. The hope was not realized, and on his return home it was found that there were signs of more serious and deep-seated disease, and for the past few weeks it has been recognized by his friends that recovery could not be expected. Professor Cunningham, who was an Edinburgh student, was Demonstrator of Anatomy in the University from 1876 until 1882, when he was appointed Professor of Anatomy in the School of the Royal College of Surgeons in Ireland. In the following year he became Professor of Anatomy in the University of Dublin, an office which he only resigned in 1903 to succeed his old master, Sir William Turner, in the Chair of Anatomy in Edinburgh. Of all that Professor Cunningham did in and for Dublin and Edinburgh it is too soon to speak; it was a fine career, nobly lived in a spirit of true and chivalrous devotion to science, to the profession he adorned, and to the public weal.

THE REFORM OF THE POOR LAWS.

THE Council of the British Medical Association, at its last meeting, decided that a special Poor Law Reform Committee should be appointed to consider the reports of the Royal Commission on the Poor Laws as affecting the medical profession, and to make recommendations as to any action which should be taken by the Association. It was further decided that, for the consideration of questions affecting England and Wales, the committee should be constituted of five members nominated by the Medico-Political Committee, three by the Public Health Committee, and two by the Hospitals Committee, and this committee met last week. At the same time the Scottish Committee and the Irish Committee were each requested to consider questions specially affecting Scotland and Ireland, and to nominate two members each to the special Poor Law Reform Committee for the consideration of questions affecting the United Kingdom as a whole. As our readers are aware, the Report proper¹ is a folio volume of 1252 pages, consisting of a Majority Report filling 670 pages; memoranda and notes by individual members of the Commission, filling 48 pages, and a separate or Minority Report which contains 518 pages. In addition there has been issued the report by Dr. J. C. McVail² of an inquiry undertaken by him at the request of the Royal Commission as to the methods and results of the present system of administering indoor and outdoor medical relief, founded upon careful examination of the administration in certain selected unions; this report forms a volume of 338 pages. In May was issued the report on Ireland.³ That volume contained a statement to the effect that the complete publications of the Commission would extend to at least thirty-one volumes; it is obvious that the consideration of such a mass of material, even if for the moment we confine attention to the Majority and Minority Reports and that on England and Wales by Dr. McVail, will demand prolonged study, more especially as all the three reports contemplate a profound modification of the present system of giving relief in poverty and sickness and the co-ordination and extension of the machinery

¹ BRITISH MEDICAL JOURNAL, February 20th, p. 479, and February 27th, p. 545.

² *Ibid.*, April 3rd, p. 855.

³ *Ibid.*, May 8th, p. 1123.

for the prevention of poverty. It is hardly to be expected that the special Poor Law Reform Committee will be able to present a report containing considered recommendations in time for its discussion at the Annual Representative Meeting next month, and the subject is of such great importance and so extremely complicated that it would obviously be unwise for the Association to commit itself to any settled line of policy until the problem has been fully reviewed in all its aspects. It is not the interests of Poor Law medical officers alone that are concerned, but the whole future of the medical profession in this country is involved, as Dr. Ford Anderson points out in the address published this week (SUPPLEMENT, p. 408), which we may commend to those who have not yet commenced the study of the subject as a very excellent brief introduction to it. As he recognizes it is very desirable that the opinion of Poor Law medical officers should be ascertained at an early stage, and we may direct attention to the particulars given elsewhere of a conference of Poor Law medical officers to be held at the Guildhall, London, on July 6th, under the auspices of the Poor Law Medical Officers' Association of England and Wales to consider the report of the Royal Commission with regard to Poor Law medical relief. It is estimated that there are in the Poor Law medical service of this country between three and four thousand medical practitioners, and their status must be considerably affected by the carrying out of the proposals of either the majority or the minority of the Royal Commission: both parties in the Commission are to be represented at the conference, for Mr. Loch, who signed the Majority Report, and Mrs. Sidney Webb, who signed the Minority Report, are both to read papers.

THE STUDY OF MAN.

FROM statements published in sundry newspapers, it would appear that the larger municipalities in this country have all recently received from Mr. Arthur MacDonald, of Washington, a memorandum urging the establishment of municipal departments for the study of the criminal, pauper, and defective classes. The idea is not likely to be acted upon for the present, at any rate, as the anthropological energies of local authorities are fully absorbed by the study of children as represented by the scholars in elementary schools, but the circular lends interest to a pamphlet by the same gentleman, which has recently reached our hands. It bears the attractive title, *A Plan for the Study of Man*, and consists of 162 closely-printed pages. As far as we have been able to ascertain, it discloses no definite scheme of any sort for studying man, but, on the other hand, contains an infinity of disconnected paragraphs and quotations from other of the author's very numerous publications, and some records of examinations of adults and children. The latter lose most or all of their value, because the fashion in which they were collected is imperfectly stated. The short paragraphs are perhaps intended to direct attention to points to be studied at a laboratory of the kind advocated, and deal in a couple of hundred words or so with such subjects as defects of sight and hearing, dangers at the age of puberty, and measurements of the head. Many of the statements made are decidedly remarkable. Thus the reader, after being informed that the criminal classes contain an unusual proportion of left-handed people, is told that the finger muscles of the pickpocket are sometimes cut so that he can apply either hand with greater dexterity. A similarly valuable piece of information is that at puberty the arteries increase in length, but little in diameter, so more work is then thrown on the heart, and

if growth is hindered there is danger of the early development of consumption. More space is devoted to hypnotism than to any other subject. The author appears to have visited hypnotic clinics in various countries, and has been so much impressed thereby that apparently he would desire to see hypnotism adopted as one of the ordinary methods of dealing with unruly children in schools. Finally, it may be noted that the author indicates a belief that students of psychophysics should have a preliminary scientific training of the kind undergone by medical men, and, after reading his book, one is fully disposed to hold the same view.

MAY MARRIAGES.

How comes it that May has got the reputation of being an unlucky month for marriages? We all know that "in the Spring the young man's fancy lightly turns to thoughts of love," and the natural inference would seem to be that he would be eager to translate his thoughts into action. Vegetation begins to revive in May, and the birds sing their love songs on every spray. Yet how strong is the superstition as to the unluckiness of May marriages is shown by the fact pointed out by Sir Samuel Wilks in the *Hampstead and Highgate Express*, that whereas at the end of April a column and a half of the *Times* was occupied by announcements of weddings, with the beginning of May the list fell almost to nothing, becoming longer again in June. The superstition is older than Christianity, for it is mentioned by Ovid, who says in his *Fasti* that May was the month of the Lemuralia, or the Lemurian festivals. "These," to quote Sir Samuel Wilks, "were instituted by Romulus in honour of his brother Remus, who died in this month, and were called the Remuria. Afterwards, the letters being changed, which was a common thing amongst the Romans, they were called the Lemuria. The Lemures were the 'manes' of the dead, which wandered about as ghosts over the world, terrifying the good people and haunting the wicked. The Romans had the superstition to celebrate festivals in their honour in the month of May. The solemnities continued three nights, during which time the temples of the gods were shut and marriages prohibited. The people performed many curious ceremonies to drive the 'ghosts away.' The following are the words of the poet in his *Fasti*, the subject of which is the feasts of Rome:

Mox etiam Lemures animas dixere silentium;
Hic sensus verbi, vis ex voce erat,
Pana tamen veteres illis clansere diebus,
Ut nunc ferali tempore aperta vides,
Nec viduae tædis eadem, nec virginis apta
Tempora; quæ nupsit, non diuturna fuit.
Hæc quoque de causa, si te proverbia tangunt,
Mense matum Maio nubere vulgus ait.

Sir Samuel Wilks says that in one edition of the *Fasti* the text gives "malas" instead of "matum," which would mean that "they are bad wives who marry in May." For our own part, we should say that May marriages are most likely to be unlucky when that month of love and mellow fruitfulness weds with sapless and barren December.

HERMAPHRODITISM.

MUCH has been written recently in French medical serials about hernia of the uterus, hermaphroditic conditions associated with that form of rupture, and hermaphroditism independent of uterine hernia. Cranwell's monograph is a standard work on uterine hernia, and Cornil and Bressard, and in Germany Arnolds, have also published cases with comments on androgyny, and some notice of these contributions to medical literature has already appeared in the

JOURNAL. Bégouin of Bordeaux has recently published a report of a very doubtful case.¹ He observes that in about 96 per cent. of all instances of pseudo-hermaphroditism it is a male that is taken for a female on account of a perineo-scrotal hypospadias, yet he considers that the subject about whom he writes, brought up as a boy, was really a girl. A child aged 7 was brought to Bégouin in the spring of 1904 on account of an abdominal tumour which had been observed for six months. The child had grown rapidly during the past year; the penis was large, but the mammae had also developed, and had attained the size normally observed in a girl of about 13 years of age. There was much hair on the pubes, hypospadias was detected, and while the left side of the scrotum was empty, there was a right scrotal hernia including a body which felt like a testis. A solid tumour occupied the hypogastrium, rising above the umbilicus; it lay more to the left than to the right of the middle line. This movable hard tumour, as big as a fetal head, felt like a fibroma of the ovary, or a pedunculated uterine fibro-myoma, and Bégouin states that had he known the true sex of the patient as was afterwards revealed he would have diagnosed accordingly. He believed that the child was a boy, and therefore suspected that the tumour was a fibroma of the mesentery, a subject on which he is known to be an expert.² He opened the abdominal cavity and discovered that the tumour was a fibro-myosarcoma of the left ovary, connected by perfectly normal relations with the uterus; the left round ligament and Fallopian tube ran over its anterior aspect, and the left broad ligament was not opened up. The cervix of the uterus was reduced to a thin fibrous band, which was divided together with the broad ligament, and then the tumour came away. No ovary, Fallopian tube, or broad ligament could be found in the right side of the pelvic cavity, but when Bégouin proceeded to obliterate the inguino-scrotal hernia on the right side he found that the right Fallopian tube lay in its sac, connected with the body that Bégouin had taken on palpation to be a testis, but which was found to have all the appearances of an ovary. He reduced the right tube and ovary, not wishing to risk occurrence of the symptoms which frequently follow removal of both genital glands. The external parts were carefully examined after the patient's convalescence, and then it was seen that the scrotum ran forwards, passing over the front of the root of the short though well-developed penis-like body which Bégouin considers to be a clitoris, the more so because the urethra did not run along under its lower border as in hypospadias in the male, but passed upwards straight into the bladder, just as in the normal female. There was not even a lemuroid clitoris traversed by the urethra. Bégouin saw and examined his patient last November, four and a half years after the operation. He admits that the child looked like a boy. Bégouin calls "him" *il* more than once in this second report, and notes that the mammae were much less developed than in 1904. "He" stood 4 ft. 10½ in. in "his" stockings and was very muscular. "He" is now at the top of "his" class in a boys' school and excels in active sports; "his" parents have decided to let nothing be known about "his" condition, and to take no steps to alter "his" *état civil*, so that the "girl" will probably have to serve "his" term in the army. With all respect to Bégouin, we must add, in conclusion, that many authorities will hardly be con-

vinced that this subject is a female. The left "ovary," converted into a large tumour, contained no ovarian elements; this is purely negative evidence, as the same may be the case in double solid ovarian tumours of the ovaries. But the right "ovary" was not removed, so that we cannot feel sure that it was an ovary at all. A rudimentary Fallopian tube, and even a uterine cornu have been found connected with a true testis. In a doubtful case the microscope alone can decide what is the true nature of the genital gland.

ATTEMPTS TO REDUCE VACCINATION FEES.

A VACANCY occurred recently in the office of public vaccinator for one of the districts of Newcastle, and in deference, it would appear, to the wishes of the local ratepayers' association a proposal was made to reduce the fee to 2s. 6d., and was only rejected on a close division. A similar proposal was made a few years ago, and then also was defeated only by a narrow majority. The ratepayers' association has not acknowledged either defeat, and at the meeting of the board of guardians at which the appointment was to be made the other day, a deputation from the ratepayers' association attended and represented the views of that body. The chairman informed the deputation that it was too late as the board had already decided that the fee should be 4s. 6d.; nine candidates had sent in their names, and of these eight attended and were interviewed by the board; each was asked whether he would take the appointment at a lower figure, and the reply was to the effect that the candidate was resolved to be guided by the views of the British Medical Association. The Division, as may have been observed by attentive readers of the JOURNAL, had already taken action in the matter, and had recommended that the reduction of the fees ought not to be accepted. The candidates have loyally abided by this opinion, and Dr. Hindhaugh was appointed at the rate of 4s. 6d. In another part of the country another Division, the Hampstead Division of the British Medical Association, has had to take similar action. At the last meeting of the Hampstead board of guardians a deputation from the Hampstead Division presented a memorial protesting against the fee of 2s. 6d. for each successful vaccination and 1s. for each name placed on the list, offered for the posts of public vaccinator in the Hampstead and Kilburn districts in advertisements recently issued. The memorial pointed out that the fees were insufficient, having regard more especially to the facts that the average number of visits for each case of successful vaccination exceeds three and a half, and that in Hampstead a relatively small number of cases was scattered over a large area, so that the amount of time required for the discharge of the duties was disproportionately great. The board resolved to refer the memorial to the Finance Committee, and the Chairman said in reply to inquiries that, owing to the action taken by the British Medical Association, no applications had been received in response to the advertisement.

FLIES AS CARRIERS OF INFECTION.

THE part played by flies in the carrying of disease germs is a question which has recently come somewhat prominently before the medical profession. A good deal of work on the subject has already been done, especially in Liverpool and New York, and last year the President of the Local Government Board authorized an investigation into the possible carriage of infection by flies, under the general supervision of Dr. S. Monckton Copeman, F.R.S., in co-operation with Professor Nuttall, F.R.S., of Cambridge. As Dr. Newsholme points out in the preface to a preliminary

¹Pseudo-hermaphroditisme masculin externe coïncidant avec un sarcome de l'ovaire. *Revue de gynéc. et de chir. abdom.*, March-April, 1905, p. 173.

²Traitement des tumeurs solides et liquides du mésopètre. *Revue de chirurgie*, vols. xviii (1838), and xix (1839).

report¹ of this investigation just published. several years will have to elapse before the relation of flies to certain diseases can be definitely ascertained, and the investigation completed, but in the meantime many interesting points crop up justifying the publication of these preliminary papers. The report contains the following: (1) How to distinguish the more important species of flies found in houses, by Mr. E. E. Austen, of the British Museum; (2) Mr. Austen's notes on flies examined during 1908; (3) Mr. Jepson's report on the breeding of the common house-fly during the winter months. In examination of sets of flies from a number of centres in London, collected on twenty-three different days at intervals varying from one to seven days, Mr. Austen found ten or eleven species, but the majority occurred seldom. The commonest species were the common house-fly, *Musca domestica*; the lesser house fly, *Homalomyia canicularis*; the blue-bottle, *Calliphora erythrocephala*, and the *Muscina stabulans*. The distinctive characters of the more important species are given in a synoptical table, and a plate of diagrams is appended. The differentiation of the insects is seen to be easy, the characteristics of the fourth longitudinal vein in the wing being one of the important points to note. The breeding grounds of the house fly are accumulations of horse manure and house refuse, and, this being so, such collections should be frequently removed or destroyed, especially during the summer months. Mr. Jepson shows by a series of experiments that flies, provided the temperature is suitable, may go on breeding during the winter months. The duration of the various stages at an average temperature of 70° F. he gives as follows: The eggs hatch in twenty-four hours, the larval period occupies eleven days, the pupal on an average ten days. He concludes that much might be done, in reducing or even exterminating flies, if isolated colonies living in certain warm places over the winter months were carefully looked for and destroyed. This certainly seems sound advice, and might in many instances be easily acted upon. The report should prove of use to the laity as well as to the medical profession, and will contribute to the more general recognition of the danger of flies.

THE MUSEUM OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE specimens added to the Museum of the Royal College of Surgeons during the present year, some 380 in number, are of exceptional interest. They are to be exhibited in the Council Room of the College on July 1st, 2nd, and 3rd. Among the more curious specimens added to the pathological series may be mentioned a part of the calcified aorta of King Menephtah, the Pharaoh of the Exodus, a very large calculus removed from the bladder of an Egyptian subject by Mr. O. Richards, a skull from one of the Cook Islands, showing extreme syphilitic lesions, another from the Gold Coast with an early condition of leontiasis, while a third from Fiji, presented by Mr. Glanville Corney, exhibits a remarkable form of calvarial periostitis. The numerous additions to the pathological series are representative of the more recent advances in surgery and morbid anatomy, and will well repay a visit. Amongst the specimens illustrating malformations, besides two sets of additions illustrating clefts of the palate and congenital defects of the heart, are three of special interest. These are the skull and brain of a "steeply-headed" child of 7 weeks, presented by

¹ Reports to the Local Government Board on Public Health and Medical Subjects (New Series, No. 5). Preliminary Reports on Flies as Carriers of Infection. London: Wyman and Sons, Limited; Edinburgh: Oliver and Boyd, Tweeddale Court; Dublin: E. Ponsonby, 909, 2d.

Dr. George Carpenter; the pelvic viscera of an individual regarded in life as a woman, but in whom the sexual and accessory sexual glands were found to be completely absent; and the dilated rectum of a child, operated on some years previously for atresia ani, presented by Mr. P. Daniels. Important additions to the series illustrating the anatomy and physiology of the body will also be shown. The great collection illustrating the diseases of the ancient inhabitants of Upper Egypt, which formed a striking feature of the exhibition given last year, is now suitably arranged in the museum and supplied with a card catalogue, and open to the inspection of all.

THE MEDICAL DEPARTMENT OF THE BOARD OF EDUCATION.

BRADFORD has exerted a quite remarkable influence on the medical aspects of education. A great deal of the pioneer work in connexion with the medical inspection and examination of children in elementary schools was done in Bradford by Dr. James Kerr. Dr. Kerr became medical officer to the London County Council, and the value of his work is well known to all educational experts. His successor in Bradford (Dr. Ralph Crowley) has now received the appointment of assistant medical officer to the Medical Department of the Board of Education. All who know Dr. Crowley will acknowledge that his promotion is well deserved, and there is no doubt that his talents and ability will be utilized to the greatest advantage in promoting physical and mental efficiency in the elementary schools of the country.

THE BRISBANE AND QUEENSLAND BRANCH.

WE regret to announce that Dr. Archibald Birt Brockway has resigned the office of Honorary Secretary to the Queensland Branch of the British Medical Association, which he has held since 1901. During that period the membership of the Branch has increased from 127 to 160. Its present flourishing condition is due largely to the untiring energy and self-sacrificing devotion which Dr. Brockway brought to the discharge of his duties. Not only the Branch which he served so well, but the whole Association, owes him a debt of thanks for his work, in which he has been ably assisted during the last three or four years by Miss Earnshaw. Dr. Brockway is succeeded by Dr. Donald Cameron, of Brisbane, under whose fostering care there is every reason to expect that the Branch will continue to grow and prosper.

Medical Notes in Parliament.

The Local Government Board Vote. Children.

DURING the consideration of this vote last week on Thursday Lord Edward Talbot raised the question of keeping children in workhouses, and advocated their removal from such surroundings by boarding out. Mr. Long, who followed, paid a compliment to the administration of Mr. Burns, and urged that there should be no undue haste in deciding on action with regard to the two reports of the Poor Law Commission. Mr. L. Haslam advocated the appointment of women in each union to supervise the boarded-out children. Mr. W. Crooks, who followed, made an interesting speech, in which he criticized all the plans hitherto adopted for dealing with the workhouse children, and urged that they ought, as a rule, never to come into the house, but that the guardians should take steps to prevent widows' homes from being broken up. The mother was the proper guardian, and a better could never be got. If adequate out-relief was allowed, it would not be more costly, and would be infinitely better for the children. He also advocated that imbecile children should be kept in separate homes up to 21 years of age, and that all Poor Law children should be under the Education

Authority as regards schooling. Mr. D. Maclean also spoke on the treatment of children, and urged that in the maternity wards some classification should be made so as to separate the young mothers from vicious inmates. Several other members having raised other points as regards the treatment of children.

Vaccination.

Mr. Lupton made a characteristic speech, in which he said that the President of the Local Government Board scattered with his right hand the blessing of ventilation, pure air, good drainage, and everything that could confer happiness on the community, while with his left hand he scattered poison, and strangled all the good that other departments under his control effected. Why should he go on scattering poison and persist in impregnating the blood of the people with it? He knew perfectly well—he must know—that there was a daily breaking of the law; that they were daily supplying stuff which was called “glycerinated calf lymph.” They said that it could not do any harm, because they had looked through the calves. One would like to know whether the Local Government Board would persist in requiring, as it did some years ago, that the vaccinators should make four big marks on the body of the poor little infant. He would like to know whether an inspector, when he went to examine the arms of children who had been vaccinated, looked to see whether they had got these four big marks, and whether the bonus was given for torturing infants. Dr. Monckton Copeman, a well-known authority and a most scientific inspector, said that big marks were an exploded fallacy, that the marks were made by what he described as extraneous organisms, and that you might have perfectly good vaccination with hardly a perceptible mark. Mr. Lupton also cited a case in which injury was alleged to have been done by too early vaccination.

Tuberculosis.

Mr. J. W. Wilson next referred to the movement to combat the spread of tuberculosis, and urged the publication of elementary instructions as to how to act when phthisis occurs in a family.

Mr. Burns's Reply.

After some remarks on the administration of the Adulteration Acts, more especially with reference to margarine and butter, by Mr. Kilbride, Mr. Burns replied to the several speeches, and said that there were in England 233,000 children wholly or partly supported by rates in and outside Poor Law institutions. Of that total, 70,000 were boarded out in cottage homes, barrack schools, scattered homes, district schools, and workhouses and infirmaries. A child in a district school cost from 10s. to 13s. 7d. per week; in a barrack school the cost was from 10s. 4d. to 18s. 8d.; in cottage homes from 12s. 9d. to 25s. 2d. in a few cases; and in the scattered homes 8s. 6d. to 11s. 2d. So far as money was concerned, public benevolence towards the children dependent on the State was larger and more generous than in any other country. Of all the indoor children in England and Wales 58 per cent. were in cottage homes, scattered homes, or in separate institutions where their bodily or mental peculiarities could be more satisfactorily administered to than they could be in the old-fashioned general workhouse. He should not rest until the whole of the sick children in London workhouses and infirmaries, and also in the provinces, were transferred from workhouses and infirmaries to institutions in which they could be better cared for than they could be in those institutions, however good they might be. As regards boarding-out, he proposed to issue an Order to bring the children within the union under the inspection of the Local Government Board inspectors, and also under the supervision of visiting officers and other kindly disposed persons. An Order would be issued under which the guardians would be able to carry this out, and where necessary appoint female officers. As regards the transference of the Poor Law schools to the Education Department, he thought there was something in it. As regards tuberculosis, he thought much good would result from the Order already issued, and they intended to follow it up. The Notification of Births Act had been adopted by 140 towns and boroughs. The Registrar-General said that 84 large towns had adopted it, and that of the 140 which had altogether adopted it 18 of them were metropolitan boroughs. The City of London

had adopted it, and he was pressing the remainder of the metropolitan boroughs to adopt it. If they did not do so he should take steps to force them. He was convinced that the Notification of Births Act, the regulations dealing with tuberculosis, and those relating to outdoor relief, would do a great deal towards stamping out some of the worst diseases. He would consider how instructions might be issued as regards tuberculosis and its prevention. He was glad to say that the general infant mortality of the whole country had shown a direction downward. It had fallen from 140 or 150 to 113 throughout the whole country. He believed that the steps which had been taken through the Notification of Births Act would tend still more to the rapid diminution of infant mortality. Unfortunately, in some of the Midland and Northern towns, where too many married women go to work under conditions and at a time when they ought to be at home, and frequently resumed work when they should be nourishing themselves and sustaining their children by natural means, the infant mortality was still too high. That aspect of infant mortality had not been raised, but the infant mortality for which the Local Government Board was responsible was being dealt with. The Medical Department of the Local Government Board was going to follow up the excellent Report on Public Health and Social Conditions which had recently come from the Department, and intended to produce a special Report on Infant Mortality viewed from several aspects which had not been dealt with in the past. That inquiry was now going on, and the excellent books which had recently been published would be supplemented by a special report of the investigation into infant mortality. As regards the death-rate which happened occasionally, and, he admitted, too frequently in some of the worst districts, in the workhouses and maternity wards and infirmaries, it was only right hon. members should temper their reception of certain allegations made recently in various newspapers by a knowledge of facts and circumstances as to the death-rate of infants born, often to women who had been cruelly treated and beaten, overworked and badly cared for before they came into the workhouse, and very often absolutely in the process or immediately before the act of childbirth itself. It stood to reason that a child whose father and mother lived under the conditions from which this type of child was drawn could not be expected to live or to be as strong as children differently placed. Where 60 per cent. or 70 per cent. of the women who were in the maternity wards in London and other workhouses were illegitimate mothers, as against only 4 per cent. of illegitimate mothers outside, it stood to reason that the children who were the offspring of such women could not expect to live, or, if they lived, to be as strong as the children of legitimate parents. The hon. member for Merthyr Tydvil (Mr. Keir Hardie) shook his head. Did he agree with Savage, the poet, who himself was illegitimate, that illegitimate children were the sickly fruit of fond compliance? No; he could not. Did he take the converse view that illegitimate children, according to the same poet, were stamped in the mint of Nature's glowing ecstasy? Certainly not. What were the facts? The facts were that illegitimacy not only connoted moral delinquency, but also indicated physical degeneracy. (Mr. John Ward here interjected, “Nonsense.”) If one visited the maternity wards it was easy to see how lack of food, overwork, and ill usage borne by the mothers had destroyed the power of the illegitimate child to resist disease. Hence during the first week of life the mortality of such children was greater in such wards than outside, but afterwards the infants improved rapidly under good feeding and good nursing with regular medical care. The matter would receive his best attention, but he was convinced that in the interests of the race the prenatal conditions of the children must be improved by saving the mothers from overwork, bad treatment, and bad food. The debate afterwards dealt mainly with unemployment, and late at night the vote was agreed to without a division.

The Spirit Duty and Medical Preparations.—Mr. Fell asked the Chancellor of the Exchequer if the additional duties proposed to be levied on chloroform, ether, and collodion were to be imposed for the purpose of raising further revenue or for the purpose of protecting whisky and other

potable spirits from unfair competition? Mr. Lloyd George said that he was afraid that he did not quite understand the hon. member's question. If he meant to imply that there was any serious risk of chloroform becoming a substitute for whisky and other potable spirits, the supposition, if he would pardon him saying so, seemed to be somewhat absurd. Mr. Fell asked what was the object of making the tax on colloidon and chloroform 6s. and on whisky 3s. 6d. Mr. Lloyd George said it was not a duty on products. It was purely a duty on spirits, and it was to meet the practical difficulty of exercising the necessary supervision in every chemist shop, and of making special exemption of small amounts of spirit included in these separate preparations. Mr. T. F. Richards also asked whether the extra duty of 3s. 9d. per gallon on spirits would mean 6s. per gallon extra duty on rectified spirits of wine, so largely used in pharmacy, in the preparation of medicines, ether, chloroform, sal volatile, balsam, tinctures, etc.; whether he was aware that wholesale druggists were already charging 6s. per gallon extra; and whether, in these circumstances, he could relieve the friendly societies' medical associations by exempting spirits used for medicinal purposes only. Mr. Lloyd George replied that he was aware of the fact mentioned, and he had given the matter very sympathetic consideration. He would have been glad had it been feasible to exempt from the additional taxation spirits used for medicinal purposes only, but, as he had already explained to the House, the practical difficulties were very serious.

The Indian Medical Service.—Mr. Kettle asked the Under Secretary for India whether, in pursuance of the scheme of reform outlined in the paper lately presented to Parliament, Indian medical men, not belonging to the Indian Medical Service, would be appointed to such posts as those of surgeon-general, professor in the medical colleges, physician or surgeon in Government hospitals, chemical examiner, sanitary commissioner, and the like, or whether it was proposed to appoint native Indians only to posts of minor importance? Mr. Hobhouse answered that the title of surgeon-general implied membership of the Indian Medical Service; as regards the other classes of posts mentioned, it would be seen from the published correspondence that the policy laid down by the Secretary of State contemplated a gradual extension, without restriction as to posts, of the employment of civil medical practitioners recruited in India. The extent to which this policy could be carried into effect, and the particular posts to which it could be applied, must necessarily depend largely on the qualifications found in the independent medical profession, from which it was intended that vacancies should be filled. As regards an inquiry whether the assistant surgeons in the General Hospital and Eye Hospital, Madras, were given no opportunity of performing major operations, Mr. Hobhouse said that the Secretary of State had no information, but would inquire.

Mosquito Extirpation in Egypt (Malaria).—Mr. Ramsay MacDonald asked the Secretary of State for Foreign Affairs whether early in 1907, under the supervision of Dr. Hugh Ross, steps were taken to extirpate malaria-breeding mosquitos from the district of Ghezireh, in Cairo; whether, after Dr. Ross's resignation, there were frequent changes of the Europeans who were in charge of the work; whether it was ultimately placed under the supervision of a native cabdriver, who had been coachman to the late adviser to the Minister of the Interior; whether, as a result, the campaign collapsed after the rising of the Nile last October; whether the Foreign Office was aware of any complaints being made that the malarial staff in Cairo was now altogether insufficient for its work; and whether, in view of the results obtained under Dr. Ross's supervision and of the importance of this work to the health of the city, the Egyptian Government would be communicated with on the subject. Sir E. Grey said that Dr. H. C. Ross was instructed in December, 1906, to take measures for the destruction of malaria-breeding mosquitos in part of Cairo, and shortly afterwards at Heluan and in other quarters of Cairo. He was aware that after Dr. Ross's resignation the post which he had filled was given to an officer of the Royal Army Medical Corps, but had no information as to whether any other European was afterwards appointed to it. The latest information in his

possession related to the month of June, 1908, and was to the effect that at that time the work at Heluan was being very efficiently supervised by a native employee. He had no information as to the collapse of the campaign beyond a statement made by Dr. Ross in a letter to the *Times* that a report to that effect had reached him, nor had he heard any complaints as to the insufficiency of the staff employed on this work in Cairo. He had no reason to doubt that the Egyptian Government was continuing to use its best efforts to stamp out malaria, and he therefore saw no necessity for the interference of His Majesty's Government in the matter. He would, however, make inquiries.

Fever in King's County.—Mr. Reddy asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that an outbreak of fever had recently taken place in Clonliff, Ferbane dispensary district, King's County, and that up to the present four deaths had occurred; would he state what time elapsed between the date of notification by the Member for the Division and the arrival of the inspector on the scene; whether he was aware that the spread of fever was due to the fact that not until after a fatal case did the people find out that fever was the cause of death; and, seeing that this had been the second outbreak in this district, would he grant sworn inquiry into this matter in order to give confidence to the people who were terror stricken? Mr. Birrell answered that he was informed by the Local Government Board in Ireland that there were 16 cases of enteric fever last month, at the place mentioned, but the Board did not know the exact number of deaths which had occurred. He understood that the hon. member communicated with the Board on May 25th, and that the medical inspector visited the district on May 28th. The first recognized case of the series was seen by the medical officer of health on May 15th, when he suspected the water supply to be the source of infection, and a sample of water sent for analysis had been found to be polluted. The medical officer appeared to the Board to have taken all reasonable precautions in connexion with the outbreak, which was now probably at an end, as no case was reported to have occurred since May 26th. The Board had brought the sanitary requirements of the locality under the notice of the district council, and had urged them to provide a proper water supply. There was nothing in the case calling for a sworn inquiry. On Tuesday Mr. Reddy pressed again for a sworn inquiry, on the grounds that the outbreak was due to the incompetence of the medical officer, and that it was the second outbreak of the kind. Mr. Birrell replied that in the opinion of the Local Government Board no blame attached to the medical officer of health in connexion with this matter. The previous outbreak of fever in this district had occurred some fifteen years ago. He had already stated that there was nothing in the case calling for a sworn inquiry.

Postal Servants (Vaccination).—Mr. T. F. Richards asked the Postmaster-General whether he was aware that the medical men attached to his department were refusing to accept persons for employment unless they could exhibit good marks of primary and secondary vaccination; and whether this was done with his sanction. Mr. Buxton replied that candidates for employment in the Post Office who had a conscientious objection to revaccination were allowed exemption therefrom on making a statutory declaration to the effect that they conscientiously believed that revaccination would be prejudicial to their health. Primary vaccination was, however, necessary. There was no reason to suppose that the rules were not properly observed; but if any case, thought to have been improperly dealt with, was brought to his notice, he would have inquiry made.

Vivisection: Report of Royal Commission.—In answer to Lord Robert Cecil, Mr. Gladstone stated last week that he was unable at the present time to say when the Royal Commission would make its report, but he understood that there had been no unreasonable delay in the proceedings.

Administration of Anaesthetics.—On Tuesday Dr. Cooper introduced a bill to regulate the administration of anaesthetics.

England and Wales.

[FROM OUR SPECIAL CORRESPONDENTS.]

YORKSHIRE.

THE MEDICAL OFFICERSHIP AT EASTBY SANATORIUM.

THE Bradford Poor Law Guardians recently offered the medical officership of this sanatorium to Dr. Margaret C. Macdonald, who has been acting for some time past as assistant medical officer to their workhouse. Dr. Macdonald's salary at the workhouse was £130 a year, with residence, rations, and washing. After resigning the latter post Dr. Macdonald discovered that the guardians were only willing to pay her £120 at the sanatorium, and very properly declined it. It is to be hoped that the guardians will recognize the excellent work done by Dr. Macdonald and give her at least the same salary as she received formerly.

BRADFORD BATHS AND ELECTRICAL TREATMENT.

Two or three years ago the Baths Committee of the Bradford Corporation proposed to instal high-frequency treatment at the Bradford Central Baths. The Bradford Division opposed the proposition, and a deputation from the Division interviewed the chairman and members of the committee, who finally agreed not to make the installation. Recently it was by chance learnt that the proposal has been revived, and a letter of remonstrance was sent to the Chairman of the Baths Committee. At his request the Division has appointed a deputation to meet the committee, and it is to be hoped that the Baths Committee will again give up this undesirable proposal. Facilities exist in the city for high-frequency treatment at the Royal Infirmary for the poorer classes, and under private medical supervision for those who are able to pay. The extension of the medical treatment of disease by bath attendants is to be deprecated.

TYPHOID FEVER IN ROTHERHAM.

Typoid fever is endemic in the county borough of Rotherham, and in order to ascertain whether any special conditions capable of amendment are responsible for the continued prevalence of the disease the Local Government Board recently commissioned Dr. R. Deane Sweeting to make some inquiries as to the sanitary administration. The report upon his investigations has just been published, and is a valuable addition to the epidemiological records of the Board. During the sixteen years 1892-1907 the number of cases of the disease notified in the borough averaged 66, the lowest number in any one year being 42 and the highest 101. There have rarely been distinct outbreaks, so that Dr. Sweeting was able to eliminate as possible causes water supplies, or milk supplies, or articles of food such as shellfish, fried fish, celery, or watercress. Although the town is well sewered and is provided with suitable outfall works, there are still in existence over 2,000 midden privies of an objectionable type. They are for the most part open, sunk below the level of the ground with unbricked floors, and many are of huge dimensions. Provision is made in a private Act of Parliament for the rapid conversion of these very objectionable structures, and the corporation is empowered to pay a portion of the cost of such conversion, but for some reason or other advantage has not been taken of the Act. Dr. Sweeting recommends greater activity in the direction of converting the existing privies into waterclosets. He found that in 1906-8, of the houses provided with waterclosets, 16.3 per cent. were infected with typhoid fever, while of those provided with privies 21.3 per cent. were infected. Other causative factors were connected with defective administration. They included inadequate scavenging and disposal of refuse, insanitary conditions of back yards, badly ventilated houses, incomplete disinfection of infected articles, and the undue number of patients nursed in their own homes. Dr. Sweeting pays a well-merited tribute to the excellent services rendered by the medical officer of health (Dr. Alfred Robinson), and points out that the advice tendered in annual and special reports has not always been followed by the borough council.

It appears that Dr. Robinson, though in name the head of the sanitary department of the borough, divides his

jurisdiction with the chief sanitary inspector. This is a condition which can only act to the detriment of the town, and the council ought at the earliest opportunity carry out the recommendation of Dr. Sweeting, and make the medical officer of health *de facto* as well as *de jure* the single head of the sanitary department.

CUMBERLAND.

PROPOSED SANATORIUM FOR SCHOOL CHILDREN.

At a conference of delegates from the education authorities of Carlisle, Cumberland, Workington, and Whitehaven, from the committee of the Blencathra Sanatorium, and from the Charity Organization Society, held recently in Carlisle, it was resolved that it was desirable to establish an open-air boarding school for children of poor parents suffering from tuberculosis in an early stage in Cumberland. Dr. Morison stated that last year 19 cases of definite phthisis were found among 1,513 children examined in Cumberland, a proportion rather over 1 per cent. A committee was appointed to consider the cost and details of the scheme, and to report to a future meeting.

LONDON.

WEST AFRICAN MEDICAL STAFF DINNER.

The summer dinner of the West African Medical Staff took place on June 21st at the New Gaiety Restaurant, London. Dr. W. Prout, C.M.G., occupied the chair, and among the guests were Mr. R. L. Antrobus, C.B., Mr. James Cantlie of the London School of Tropical Medicine, Mr. A. Fiddian of the West African Department of the Colonial Office, and the Hon. H. M. Brandford Griffith, Colonial Secretary, Gambia. In the course of the evening Mr. Antrobus, in responding to the toast of "The Guests," had something to say as to the future of the West African Medical Staff. Naturally he spoke in guarded terms, but it could be gathered that the decision of the Secretary of State on the multiple questions which have been so long at issue will prove to be of a more or less satisfactory nature. The Secretary of State has at present under consideration two reports—namely, that of the Departmental Committee which commenced its inquiry at the beginning of this year, and that on the sanitation of the West African Colonies prepared at the request of the Colonial Office by Professor Simpson during his expedition to West Africa last year. It seems probable that the Secretary of State will not be found to have accepted the recommendations of the Departmental Committee in their entirety, but, at any rate, some of the larger defects in the present administration of the corps will be removed, and the arrangements as to pay and allowances be so modified as to make the prospects of medical officers on the coast more hopeful than they are at present. But even more satisfactory in one way is the prospect of the establishment of a board of a general advisory character but charged primarily with the duty of laying down a sanitary programme and of securing its execution. Poorness of prospects and superfluous irritations due to faulty administrative methods have certainly counted for a good deal in creating the feeling of dissatisfaction which has prevailed among medical officers of the West African Medical Staff for the last two or three years, but to their credit be it said that another factor has been equally potent in that direction. The development of tropical medicine makes now feasible much that was formerly impossible, and has opened up for tropical countries a vista such as never before existed. Utilization of their immense resources in the way of natural products is no longer necessarily and inevitably accompanied by equally great sacrifices of human life. The fact that this is the case greatly increases the responsibilities of medical men working in the tropics, and to fulfil these adequately—to turn the existence of this fresh knowledge to the advantage of their white and coloured patients—demands from the West African Medical Staff, as was suggested by Dr. Prout in the few earnest sentences he addressed more particularly to its younger members, more self-forgetting devotion to practical and scientific work than ever. Nevertheless, however much these officers may strive, their efforts must be futile unless encouraged by local administrators, and co-ordination and continuity of work are

secured. So far there have been grave defects in all these directions, and the recognition by medical officers that their work is more or less wasted has been followed by perfectly natural and even praiseworthy discontent.

Officers Present.

The list of retired and present officers of the West African Medical Staff attending the dinner included in addition to Drs. Front, C.M.G., A. H. Handley, C.M.G., and G. F. Barker, Dr. F. G. Hopkins, Deputy Principal Medical Officer, Drs. A. Pickels, G. S. Rutherford, and F. Manning, Senior Medical Officers; and Messrs. J. C. Bailey, D. A. Ashton, J. S. Pearsons, W. H. Peacock, R. P. Williams, J. P. Howe, W. Burrows, G. G. W. Kergevin, W. F. Taylor, H. G. McKinney, G. F. W. Ford, E. W. Graham, E. J. Tynan, J. Cross, E. C. Eliot, J. C. Franklin, F. J. A. Beringer, E. J. Kelleher, and P. M. Tobit.

WALES.

SANITARY INSPECTORS' ASSOCIATION.

The sessional meeting of the South Wales and Monmouthshire Branch of the Sanitary Inspectors' Association of Great Britain was held at Barry Dock on June 12th. The President, Dr. W. Williams, County Medical Officer for Glamorgan, was unavoidably absent through illness, and a telegram of sympathy was forwarded to him expressing the hope that he will speedily recover. Dr. Williams has been president of the centre since its inception, and he has always taken the keenest interest in the welfare of the sanitary inspector, and therefore his absence from the meeting was very much felt. Mr. Torloff, Clerk to the Barry Urban District Council, was voted to the chair. Chief Inspector S. B. Sommerfeld read an interesting paper on the sanitary progress of Barry, in which he pointed out that the public abattoir was one of the most modern in the country, and the town's sewerage arrangements excellent. The death-rate of the town had decreased from 17.1 to 11.7 per 1,000 of the population, the reduction being principally due to improved sanitation. Inspector Hookley, Chief Port Sanitary Inspector, followed with a practical paper on food inspection. The delegates were entertained to luncheon by the District Council, the chair being taken by Dr. P. J. O'Donnell, Chairman of the Health Committee. Visits were afterwards made to the public abattoir, local hospitals, and the municipal buildings, a most enjoyable day having been spent.

COLLIERS AND DOCTORS.

The following paragraph appeared in the *South Wales Daily News* of June 10th:

The doctors' question at Llanbradach has been settled at last, and to the satisfaction of the workmen, but apparently to the dissatisfaction of the local medical men. The local medical men endeavoured to enforce the system of payment of 3d. in the £, instead of 5d. per week per man. This brought about the deadlock, and the doctors gave notice to terminate their agreement, and this expired last week. The workmen's committee have now, much to the indignation of the medical fraternity, appointed Dr. Charles Hawkins of Caerphilly as their medical man on the old system—that is, 5d. per man.

The *South Wales Daily News* of the next day contained the following explanation:

With reference to the doctors' question at Llanbradach, it should be explained that while Dr. Charles T. Hawkins (Caerphilly) has been appointed under the old system of payment of 5d. per member per week, this is only by a minority of the workmen. The majority of the workmen have signed on the new system enforced by the local medical men, who gave notice to terminate their agreement, this system being 3d. in the £ per man.

Scotland.

[FROM OUR SPECIAL CORRESPONDENTS.]

MEDICAL INSPECTION OF SCHOOL CHILDREN.

The Edinburgh School Board, on June 21st, agreed to appoint two assistants to their medical officer, a male assistant at a salary of £250 and a female at a salary of £200 a year, to give their whole time to the work of the board. It was also agreed to appoint two nurses at a salary of £60 per annum each.

Dr. J. Hally Meikle, medical officer to the School Board, makes the following recommendations in his report for 1907-1908:

1. More strict inspection for and more stringent methods of dealing with dirty and verminous children. The appointment of the school nurse would secure the first, and there was ample work to be done. The second would be secured by taking advantage of the powers given under the new Education Act.
2. The following up of cases and home visits to see that any treatment recommended was carried out. This work would again fall to the school nurse. There were many parents anxious to do their best for their children, but ignorant of how to do it.
3. Schools for special skin diseases, chiefly favus and ringworm, a subject at present under the consideration of the board.
4. Relaxation of quarantine regulations for certain minor infectious diseases.
5. That the infectious disease history of pupils be recorded on their entrance forms.

The Earl of Wemyss, who is Chairman of Aberlady School Board, has submitted a resolution to the board on the subject of medical inspection of school children in East Lothian. The County Committee had recently issued a circular letter on the subject, recommending the appointment of a special medical officer for the county for school inspection. The resolution of Lord Wemyss is to the effect that the appointment of a county medical officer specially for the inspection of school children is unequalled for and would be a needless addition to the heavy school charges now borne by the ratepayer—charges which, when free education was first established, the ratepayer was assured would never exceed 3d. in the £—and also that before any steps are taken in furtherance of the committee's report full information be given of the total cost of the committee's plans and of the contribution thereto required from each individual board. The resolution has been adopted by the Aberlady Board.

MEDICAL TUTORIAL FELLOWSHIPS AT GLASGOW.

By the will of the late Dr. John Hall, of London, the medical side of Glasgow University will eventually come in for a large estate which is expected to realize over £35,000. Dr. Hall, who was an old graduate of Glasgow University, died on April 17th last, leaving an estate of the gross value of £88,366, subject to the life interest of his sister. A number of London medical and other charities receive donations, but the bulk of the trust goes to the Senate of Glasgow University as an endowment for the foundation of tutorial fellowships in connexion with the chairs of medicine, surgery, and midwifery. These are to be known as Hall Tutorial Fellowships, and are to be open to graduates of Glasgow University of not more than four years' standing. The election is to be made by a committee of the professors of the three subjects named, after examination (either a special examination or part of the graduation examination). Each fellowship is to be of the value of £200, tenable for three years. As many fellowships are to be founded as the income will permit; any surplus of income being applied for providing models, instruments, etc., for teaching purposes, or in providing prizes for deserving students. During the tenure of a fellowship the holder must not hold any other bursary scholarship or other educational endowment, nor engage in private practice or private teaching. He must reside within three miles of the university and must devote his whole time to practical instruction of students under the direction of the professors.

THE CHAIR OF SURGERY IN EDINBURGH.

The vacancy in the Chair of Surgery in the University of Edinburgh, caused by the regretted resignation of Professor Chiene owing to ill health, will shortly be filled. The patronage is vested in the Curators, and formal notice will be found in our advertisement columns that applications with relative testimonials must be lodged with Mr. R. Herbert Johnston, Secretary to the Curators, 4, Albany Place, Edinburgh, on or before July 15th.

THE MILK AND DAIRIES BILLS.

The Public Health Committee of Edinburgh Town Council have had under consideration the Milk and Dairies (Scotland) Bill and the Milk Control (Scotland) Bill, abstracts of which were published in the SUPPLEMENT of June 12th. It was pointed out to the committee that the powers of local authorities which would be repealed by the Milk and Dairies Bill were in many respects superior to those contained in it, and it was agreed to approach other local authorities with the view of making arrangements for amending the bill in the direction desired.

HOSPITAL TREATMENT OF PHTHISIS.

At a meeting of the Town Council of Edinburgh on June 15th it was agreed to increase the authorized number of beds set apart for phthisis cases in Colinton Mains Hospital from 50 to 62, and that six pavilions to accommodate 12 patients be provided at a probable cost of £120, the estimated annual cost of treating 12 additional patients being £250.

PAROCHIAL MEDICAL OFFICERS IN THE HIGHLANDS AND ISLANDS.

We have received a letter from a parochial medical officer in one of the western islands of Scotland, giving his experience of the work he is expected to do and the hardships he has to undergo for a salary of £126 per annum. As the experience of this medical officer is that of many of the medical officers in the Highlands and islands of Scotland, the publication of the facts should serve as a warning to others. The advertisements which appear from time to time asking for candidates for these posts may seem to young and inexperienced graduates rather tempting, for besides the salary offered for the parochial appointments the advertisement generally states that there is a free house and good scope for private practice.

Our correspondent tells us that in his case the salary, including parochial, lunacy, vaccination, school and public health, work was £126 per annum. The island contains a population of 6,000, is 40 miles long, 10 to 12 miles at its broadest part, and 2 miles at the narrowest. Vaccinations had to be done, some of them 40 miles from our correspondent's house, necessitating long and trying journeys, with the expenses of the same, including night's lodging and board and fares by steamer, or horse hiring when available. No travelling expenses were allowed. In the first six months our correspondent held the appointment he had a list of over 100 vaccinations, for which he received 40s., the allowance for vaccination being £4 a year, the medical officer not being paid so much for each vaccination. Pauper lunatics have to be visited once a quarter, for which the doctor gets £6 per annum. Forty-eight visits were paid to these cases, at an average distance of 10 miles; this works out at about 4s. a visit. No travelling expenses are allowed.

The house provided for the medical officer on this island was leaking in every room and was in a bad state of repair. The difficulty of getting provisions and fresh food is also a serious factor in connexion with these appointments, especially during the winter months, tinned provisions being the mainstay. Fuel is also a serious item of expenditure, the supply of peat to keep fires going having cost our correspondent 12s. a week.

Private practice proved a delusion and a snare. The scheme under which it is worked is that the crofters pay 6s. per annum, and if they all paid the amount would come to about £100 per annum. For this the medical officer would have about 300 families to attend residing within a radius of 20 miles. The doctor is supposed to get paid for medicines supplied, but unless the amount is prepaid he has little chance of getting it; in the experience of our correspondent only 20 per cent. of the patients paid for their medicines. Our correspondent works out the remuneration he received for some of his visits to the outlying crofters at the rate of 1d. a week; he had to walk 20 miles to see them, and either stayed at a house not possessing the most sanitary surroundings, as the olfactory organs soon discovered, or else put up at the nearest hotel, which meant, of course, the expense of board and lodging for the night.

Our correspondent states that for six months he covered an average of 400 miles a month, and mostly on foot, and there was seldom a day without a strong wind blowing, sometimes half a gale. Most of the travelling was over extremely rough footpaths, covered with stones and rocks, very steep and impassable except on foot. He calculates his out-of-pocket expenses for travelling at £50 per annum, and as he says, "combine this with a leaky house, tinned provisions, and you have as undesirable and unremunerative a place as could be found anywhere." Any one taking up an appointment in this particular island will have to pay a good deal to get there, and as his tenure is likely to be short, in a few months will have to pay a similar sum to get away. Any one bringing furniture will in all probability leave it there, as, after being knocked about

from rail to steamer and from steamer to boat, and from thence by any available means of carriage, it will hardly be worth carrying away.

We have frequently in the columns of the JOURNAL drawn attention to the hardships of the parochial medical officers in the Highlands and islands of Scotland, mainly on the ground of harsh treatment on the part of the parish councils. This is an instance not, as far as we can gather, of harsh treatment, but of a sweated medical practitioner who, doubtless thinking the salary and prospects of private practice looked good in the advertisement, resolved to give it a trial. The vicissitudes of climate combined with the amount of bodily fatigue which the medical officer is expected to go through in order to reach patients living many miles away from his house seem more than mere man is able to endure. We therefore again warn young medical men against these appointments, and if they are tempted to apply for them they should consult the Secretary of the Scottish Poor Law Medical Officers' Association, Dr. W. L. Muir, 1, Seton Terrace, Glasgow, who has all the information necessary regarding them, and who, we feel sure, will be ready to advise any young man on the subject.

Ireland.

[FROM OUR SPECIAL CORRESPONDENTS.]

EMERGENCY CASES.

At a recent meeting of the Galway Urban Council, Sir James O'Donohoe, J.P., expressed some not unnatural indignation at the working of a regulation with regard to the admission of emergency cases into workhouse infirmaries. A man was run over by a scavenging cart and was obviously seriously injured; a police sergeant was appealed to, and said that he could not remove the man without an order from the dispensary medical officer or a ticket from the relieving officer. Sir James O'Donohoe, on his own responsibility, secured a van and removed the sufferer to the county hospital, where he died two hours later. The incident illustrates one of the anachronisms of the Irish Poor Law. The police sergeant was wrong in stating that the dispensary doctor had power to send a patient to the workhouse infirmary; neither he nor the medical officer of the workhouse has such power. According to un repealed regulations, admission can only be granted by the board of guardians in session, the relieving officer, or in cases of sudden and urgent necessity by the master of the workhouse. These places upon the master the responsibility of deciding, in the absence of a line from the relieving officer, whether the case is sudden or urgent—a decision which has often been most unfairly criticized, where the master has exercised his judgement to the best of his ability but the board of guardians or the Local Government Board has taken a different view.

If a patient belongs to another union and has no friends on the board, the master is often between the hammer and the anvil. If he admits such a case the guardians fall foul of him, and if he does not, and the patient dies, the Local Government Board will probably call on him to resign; we have reported several such cases within the last few years.

The Irish Poor Law of 1837 and the existing general regulations framed upon it were designed to keep people out of the workhouse, and the attempt of the Local Government Board to modernize these institutions in face of these regulations has resulted in a hopeless muddle. Another Poor Law anachronism is that patients have to be detained in hospital long after they are fit to leave, because there is no provision for treating them as outpatients. Possibly some medical officers may do so, but they run the risk of sworn inquiries and unknown pains and penalties for transgressing the general regulations which take no cognizance of the needs of convalescents.

TUBERCULOSIS IN COUNTY DOWD.

At the annual meeting of the Down County Council the Chairman (the Right Honourable Thomas Andrews), after dealing with the various improvements which had been

brought about since the council came into office ten years ago, made an eloquent plea for further measures to prevent tuberculosis. Some 5,000 inhabitants of the county were, he said, suffering from the disease, and some 500 died each year. At imminent personal peril people rushed to the rescue in case of a threatened accident, and yet they were content to sit quietly with folded hands with 500 of their friends and neighbours dying annually from this white scourge. An example had been set at the county infirmary, unfortunately on too small a scale. They would probably soon have a disused workhouse, or an unused coastguard station; might such buildings not form a nucleus of a sanatorium? He commended the problem most earnestly to the members.

MEDICAL BENEVOLENT SOCIETY.

The annual meeting of the Belfast and County Antrim Branch of this society was held in the Medical Institute, Belfast, on June 18th, the President, Professor Symington, in the chair. Dr. Fielden, Honorary Secretary, submitted the annual report, which showed that £164 6s. 11d. had been raised. The subscriptions included £100 7s. from 139 Belfast practitioners, £27 11s. from 40 country practitioners, £6 11s. from the Belfast Medical Students' Association, and various donations. The committee expressed its hearty appreciation of the subscription from the medical students. The amount of £135 was distributed in sums of from £10 to £15. The President, in moving the adoption of the report, said efforts should not be relaxed until a minimum of £200 of annual subscriptions was reached. The society was enabled to afford assistance to extremely deserving cases. Dr. R. J. Purdon, who seconded, said that although there was a certain monotony in the annual complaint of the apathy of the profession, yet both numbers and contributions had increased; still some 70 or 80 members of the profession in Belfast and 160 in the country had never given anything. On the other hand they compared favourably with England, a much richer country, where the profession gave 1s. 4d. a head to its benevolent fund as against 3s. 7d. a head given by the Irish, or nearly 7s. 6d. from this branch. Dr. Gausson (Dunmurry) moved the election of Professor Symington as President, and Dr. Wadsworth seconded. The motion was passed with acclamation. On the motion of Dr. Calwell seconded by Dr. Maguire, the committee was elected as follows:—Sir William Whitla, Sir John Byers, Professor Lindsay, Drs. McLorinan, J. W. Taylor, Cecil Shaw, R. J. Purdon, William Gibson, Gardner Robb, Macarthur (Greyabbey), St. George (Lisburn), Gausson (Dunmurry), Greenfield (Holywood). Dr. Fielden was re-elected Honorary Secretary and Treasurer, and Dr. Calwell made reference to his indefatigable services.

Correspondence.

TREATMENT OF SCHOOL CHILDREN.

SIR,—Dr. Lauriston Shaw attributes my dissent from the views of the Branch circular to my "misapprehension of existing conditions." This has been revealed to him by the fact that in my letter I three times use the term "school doctor." "But," says Dr. Shaw, "the whole point of the trouble is that there is no school doctor." I am quite aware, and in each of my three allusions to school doctors I made it clear I was aware, that their functions were investigation and not treatment; but it seems incredible that Dr. Shaw, or any one else interested in this question, should not know that the officers are appointed and discharge their duties under the title of "school doctor."

I ventured in my letter to question whether the consultative principle would, as the circular stated, be infringed by a child being received for treatment on the notification of a school doctor. Here is Dr. Shaw's pronouncement on this subject:

One could no more act as a consultant to a medical inspector debarred from practice than to a relieving officer without a professional qualification.

I commend this doctrine to the Ethical Committee, but Dr. Shaw may be interested to learn that the officials to whom he alludes are not debarred from practice at all;

fortunately, therefore, neither Dr. Shaw or anyone else will be called upon to put his rather inhuman edict into force.

But Dr. Shaw's proposal shows the impracticability of the consultative principle, and the oppressive manner in which it might be manipulated. Although Dr. Shaw discusses the minor question, such as this "consultative principle," he does not meet the more important objections to the policy urged upon us by the Branch Council. He does not explain why a grant should be forbidden to a hospital from the London County Council while it is allowable to be accepted from the Poor Law and from other public bodies.

Nor does he explain on what grounds a school child can be refused treatment for some diseases and accepted for others. No doubt there is abuse of out-patient departments, but of all the cases that are appropriate for treatment it is these cases which we are now urged to refuse because the public has recognized their importance and offers payment in return for their treatment.—I am, etc.,

London, W., June 22nd.

SIDNEY PHILLIPS.

SIR,—I think it is to be regretted that public attention should have been called to the recent decision of Great Ormond Street Children's Hospital with regard to the treatment of London County Council school children. It is the result of precipitate action on the part of the Committee of Management without previous consultation with the Medical Committee. I have drawn the attention of the Medical Committee to the matter, and I have no doubt that the Committee of Management, who have always shown themselves exceptionally responsive to the suggestions and desires of the medical staff, will reconsider the question at the earliest opportunity.—I am, etc.,

J. HERBERT PARSONS,

London, W., June 18th.

Ophthalmic Surgeon to the Hospital.

SPEECH FRIGHT.

SIR,—Although "Celt" has concealed his identity, there are two things we have learnt about him: he can write a readable letter and he can make a good speech. The latter fact he hardly seems to be aware of, but the symptoms are too well marked to admit of mistake. There is no more certain sign of coming success than speech fright which comes short of actual brain collapse. The state of nervous tension which precedes a vocal effort is a certain sign of a mental energy that will appeal to others. The intensity of feeling which produces speech fright is identical with that which impresses an audience. Probably no one who has not suffered from speech fright has ever made a speech really worth listening to. The fact is well known to teachers of singing and of elocution. Nothing pleases them better than nervousness before a first performance. It shows that the pupil has intense feeling, and if he has feeling he can put it into his words. Meanwhile, whether it is from the habit of suppressing our feelings, or from an acquired contempt of all emotion, doctors are rarely able to make speeches, and almost as rarely (as "Celt" truly suggests) to write readable English. I remember at the first dinner of the Polyclinic Mr. Alfred Lyttelton mercilessly chafing the medical profession on being absolutely unable to make a speech. There were about 400 doctors present, and not one of them was able to controvert his statements, or to give a practical demonstration that they were unfounded.

One of the best accounts of speech fright ever written is probably that in Rider Haggard's book called *Mr. Meeson's Will*. In this case an eloquent young barrister, with the whole case at his fingers' ends, is unable in court to speak a single word. When he is in the last extremity of despair some occurrence in the court makes him laugh. The laugh causes some diversion of the circulation in the brain, and the speech fright is gone. His eloquence immediately returns. He carries the whole case through singlehanded without a hitch, and of course gains it.—I am, etc.,

London, S.W., June 16th.

J. FOSTER PALMER.

SIR,—The discussion taking place concerning the causation and cure of "Speech fright" in the columns of the BRITISH MEDICAL JOURNAL, which has gained the attention of the general public through the *Daily Mail*, will result in

incalculable evil and widespread injury being done if the remedy suggested by more than one medical correspondent—namely, the taking of opium—is seriously entertained by the average medical or lay reader, and if the advice given is not promptly met with an earnest warning that such a remedy freely recommended would surely bring consequences that would prove a thousand times worse to humanity at large than any amount of ill-delivered, and badly-prepared, but comparatively harmless after-dinner speeches that might be delivered in course of time.

The medical practitioner who is experienced and clear-minded enough knows well that to advocate opium, morphine, cocaine, and such-like drugs is to create and spread a craving more dangerous than that so commonly observed for alcohol. Cases which come before him prove indisputably that once the assuaging and exalting effect of opium is perceived by the patient there is every likelihood of a desire for more being created, which is frequently so strong that a hopeless and degenerate future is unavoidable. The drugs named give temporary relief or stimulation, but they are equally certain to render the subject weaker to resist further increased desire for more. Taking once, gently persuades the speaker to take usually, which again invites him further to take just every time he wants it—which, of course, he soon finds is very frequently. Better that there should never be another after-dinner speech delivered than that in future the excellence thereof should depend chiefly upon necessarily increasing dosage of evil-bringing medicaments. Once the opium idea gained firm root amongst the masses, the extent to which it would be carried out would soon be quite appalling. The habit might even find its way into the pulpits, and perhaps be advocated there. Think, also, of an opium-stimulated Cabinet Ministry! For if temporarily effective for one, so also good for any and all.

I am myself a public speaker and a medical practitioner, and I would suffer the misery of a hundred dry months and repeated hours of speech-suffering before I took a single opium pill.

Most drug maniacs trace their misery to medical prescriptions. I would go so far as to recommend that certain drugs should never be administered through written prescriptions, but only handed over to the patient by the doctor with instructions for taking, the patient not even knowing the name of the remedy.

Speech or stage fright is a simple neurotic symptom—usually a sudden irruption of a sense of incompetency—a manifestation of mental, nervous, or physical incapacity. It is said to be on the increase, as, indeed, are all neurotic disorders. In some cases merely the general health is a little below par, at other times the digestion is particularly at fault, here and there we find a family history of either mental or nervous conditions of various kinds, and very often in others the heart is primarily or secondarily affected. The cure for such should not be a difficult matter—and a safe one when a truly scientific one—but necessarily a slower one than the taking of a dose of opium; yet a more lasting one, constituted of medicinal and dietetic measures, acting directly and indirectly, while, of course, habits, exercise, etc., should be properly regulated. But, in addition, experience has shown that hypnotic suggestion has a most powerful and rapidly curative influence, promptly correcting, as it will, obsessions of incapacity or ideas of recurring failure, helping a halting, nervous temperament, and even further enabling general treatment to be adopted pleasantly, thoroughly, and much more efficaciously. Dr. Woods has recently referred to twenty-eight cases of "speech fright" in the BRITISH MEDICAL JOURNAL, treated merely by hypnotism alone, out of which twenty-three gave satisfactory results and five were improved.

Speakers should not forget, however, that one of the most important factors making for easy, comfortable, and self-possessed powers for public speaking is, after all, a thorough grip of the subject. Many good speakers on favourite subjects fail occasionally through over-confidence in thinking they are sure to speak well upon almost any other subject. Moreover, it must be borne in mind that a difficult subject will sometimes cause a week of worry and anxiety before the speech is made, which will gradually upset the digestion, interfere with sleep, and unsteady the nervous system, to the end that some sort of

speech failure or breakdown distresses both the speaker and the audience.

I see so much human wreckage caused by opium, morphine, and cocaine that I am simply amazed at the free advocacy of such a dangerous remedy as opium by medical correspondents in the BRITISH MEDICAL JOURNAL. I consider that doctors now thoroughly deserve the blame they are getting from clear-headed critics for actually creating drug-maniacs. It is eloquent that some of the worst cases among my patients have been medical men.—I am, etc.,

Caterham, June 16th.

HAYDN BROWN.

SIR,—It is most interesting to read the various letters on speech fright, and I think most medical practitioners have had experience of this and other varieties of the same condition. I should like to state my experience of a case of "piano fright." I have on several occasions been called upon to treat this most distressing condition. A few months ago a lady visited me and said she had been suddenly asked to accompany a very celebrated vocalist at one of our leading London concert halls. She said that she was quite certain that as soon as she made her appearance on the platform she would go off in a "dead swoon" before ever she reached the piano. I endeavoured to reassure her, and ordered her the following draught a quarter of an hour before she came on to play: Sp. am. co., 60 minims; tinct. opii, 10 minims; camphor water, 1 oz. I saw her at the hall just before the concert commenced, and she was then in a very nervous state. I never heard her play better, and she told me afterwards that the draught steadied her so thoroughly that she was not in the least nervous throughout the evening. She has had a similar draught since on more than one occasion with equally successful results.—I am, etc.,

Margate, June 15th.

SANDERSON MELLOR.

INTERNATIONAL NOTATION OF ASTIGMATISM.

SIR,—In the report of the Ophthalmological Society on page 1482 of the JOURNAL of June 19th, Mr. Jessop's note as given under the heading of "International Notation" is certainly misleading as far as the notation of astigmatism is concerned. Any one reading it would come to the conclusion that it had been agreed upon, as printed there, that henceforth

the axes should be measured and represented in the *lower* semicircle of the trial frame; the numbering of the axes should start from the middle line of the face in each eye, and proceed *downwards* and *temporally*; the zero would therefore lie at the nasal end of the semicircle, and 180° at the temporal end; 90° would be *below* and midway between these points.

This is sure to give rise to no end of confusion, and no one is likely to come to the conclusion that the Eleventh International Ophthalmological Congress held at Naples in April, to which the committee referred to had been appointed to report, almost unanimously resolved the following—namely:

That the axes should be measured and represented in the *upper* semicircle of the trial frame, that the numbering of the axes should start from the middle line of the face in each eye and proceed *upwards* and *temporally*, and that the zero would therefore be at the nasal end, 180° at the temporal end, and 90° *above* and midway between these points.

What actually occurred was this. The report of the committee (appointed at the preceding congress held in Lucerne in 1904, and consisting of seven members representing Austria, Belgium, England, France, Germany, Italy and Switzerland) had been drawn up substantially as stated in your issue of June 19th, and handed to each member of the congress on arrival at Naples. During the two days preceding the discussion of this report the committee had had ample opportunity to convince themselves that the proposal of selecting the *lower* semicircle of the trial frame would be rejected by almost every one; they therefore had resolved to agree to the selection of the *upper* semicircle for the notation of the axes. When the matter came before the well-attended meeting, the *upper* semicircle was adopted for notation by an overwhelming majority.

The notation as adopted being so completely opposite to the one published in the committee's report, it is difficult to see why the latter, after its almost unanimous rejection, should have been published at all, and especially without

the all-important addendum that it had been rejected in favour of the opposite notation.

It may be some time before the *Transactions* of the congress appear, and I beg, therefore, that you will kindly insert this correction in your next issue, in order to minimize the confusion that the statement in your last issue is bound to provoke.—I am, etc.,

Liverpool, June 19th.

KARL GROSSMANN.

EPITHELIOMA OF THE OESOPHAGUS.

SIR.—The case reported in the *JOURNAL* of June 12th by Dr. Basil Cook is an instance of a class of malignant growths well known to laryngologists, but of which little mention is generally made in the textbooks. They originate on the epithelium covering the posterior surface of the cricoid plate, and are variously described as epithelioma of the pharynx or of the oesophagus. Growing, as they do, on the cricoid, they are sometimes classed under extrinsic laryngeal cancers, but this is incorrect, for they arise on the epithelium of the alimentary canal. Mr. William Hill has urged the use of the term "party-wall cancers," but this nomenclature has the disadvantage of making no distinction between those growing on the posterior surface and those originating on the anterior aspect within the lumen of the larynx.

A point of interest about these tumours is that, while they are fairly common in the female sex, they are almost, if not quite, unknown in men. Again, they are found at a comparatively early age, frequently between 30 and 35, so that the age of Dr. Cook's patient, which was 26, is not very far from the usual range.

London, W., June 14th.

HAROLD BARWELL.

THE CAUSATION OF CANCER.

SIR.—Intending as I do to take part, at the forthcoming Belfast meeting of the Association, in the discussion on the notification of tuberculosis, I made only this morning the following preparatory note: "As in cancerous processes groups of cells may be supposed to have assumed ancestral reproductive functions, so in tuberculosis we may conceive that certain cells develop equally primitive hyperoxidizing functions." I added to my note: "This view incidentally offers an argument against the specificity of the germ plasma or germ cell."

Later on in the day I saw Dr. Marsden's letter¹ bearing the title that stands at the head of this answer. It is a pleasure therefore to me, in reply to his invitation, to express my agreement with him on several points. I am convinced, in the first place, "that the evidence so far adduced is in favour of a verdict of cancer from natural causes." I further share the impression that irritation, local or antigenic in its broadest sense, plays an important part in the development of cancer. And, lastly, I agree, as will appear from the note I have just quoted, with the view that the natural causes he invokes embrace a number of evolutionary factors. Indeed, I can add, I have long held and even advocated the opinion that most of the chronic pathological processes are susceptible of explanation on purely evolutionary principles.

The difficulties arise, as Dr. Marsden has probably anticipated or will experience, when these evolutionary doctrines are defined. No Weismannist or so-called neo-Darwinian, for instance, would consistently admit for a moment that the original destiny of the local cells could be changed, or much less even that so radical a transformation could be attributed to the environment. The Lamarckian factor of habit and use or the mnemonic principle, as Semon has recently designated this attribute, would have to be postulated.

Dr. Marsden has presumably been influenced by Mr. Francis Darwin's last Presidential address on the movements of plants. This luminous review of the latest advances in the doctrine of descent should be in the hands of every pathologist.—I am, etc.,

Nico, June 7th.

A. W. GILCHRIST, M.D.

THE DISTRIBUTION OF LONGEVITY IN ENGLAND AND WALES.

SIR.—Dr. Gordon's paper in the *JOURNAL* of June 5th loses a great deal of its value owing to his having looked

on correction for age distribution as inapplicable—a position which he takes up without giving any reasons. That it has a very decided influence on such figures as he gives is shown by considering an imaginary case of two towns, one of which has 10 per cent. and the other 90 per cent. of its population over 75 years of age; the ratios of the deaths over 75 to the deaths at all ages will manifestly not give a true comparison of the respective longevities in the two towns. Of course such an instance is absurd, but differences in age distribution will certainly have some influence, and in many cases a considerable one.

To take a case in which I have the figures worked out. Averaging over the three years 1900, 1901, and 1902 in the case of males, the deaths over 75 in England were, in round numbers, some 10 per cent. of the total deaths, in Scotland slightly less, and in Ireland some 19 per cent. Does this show that longevity in Ireland was more pronounced than in the sister kingdoms? It suggests what is the fact, that there is a larger population over 75 in Ireland, a fact which can be seen at once from the census; but are these old people healthier? By no means.

The average common death-rate for 1900, 1901, and 1902 for the United Kingdom for those aged 75 and upwards was a shade over 160 per 1,000. From this the number of deaths over 75 to be expected in each kingdom could be calculated; and while in England and Scotland fewer died than were to be expected, in Ireland there was a considerable excess.—I am, etc.,

London, W., June 7th.

F. C. MARTLEY.

MEDICAL TREATMENT OF DUODENAL ULCER.

SIR.—Mr. Leonard Bidwell's address on the surgical treatment of gastric and duodenal ulcer, published on May 29th, is so admirable, and is, in addition, so free from the unblushing condemnation of all medical treatment which disfigures many recent surgical utterances on the subject, that I hesitate to offer criticism. He will, however, I hope, forgive me for challenging his statement that

Gastro-enterostomy is also indicated in every case of duodenal ulcer as soon as it can be diagnosed, as practically no case of duodenal ulcer is permanently cured by medical means.

I shall not, I think, be contradicted when I assert that duodenal ulceration is a far commoner clinical event than is often supposed, and that *post-mortem* evidence of sound cicatricies of old duodenal ulcers is not altogether rare. The inference to be drawn from such assertion, if true, is obvious. Apart, however, from this, it is very necessary, before impugning the value of any medical treatment, to define what is meant by the term. If medical treatment means employing the archaic system of treating all cases of duodenal ulcer, acute and chronic, by "oral starvation," which also, be it noted, almost necessarily includes "rectal starvation" (since the nutrient value of even 20-ounce rectal enemata is very small), there is some justification for Mr. Bidwell's strictures. If, again, medical treatment means the adoption of the Lennartz method of feeding, or other similar half-hearted procedure, he can find further support. Even then, however, we must acknowledge that many cases diagnosed as duodenal ulcer do recover when treated on these lines and do not relapse, though some are not improved, and others—an undetermined number—improve first and then relapse.

But the time is fast approaching when it will be fully recognized that the treatment, both from the medical and the surgical standpoint, of gastric and duodenal ulcer, as of other destructive tissue lesions, must be placed on a much broader basis than at present holds, even though starvation treatment or operation are the only alternatives offered for the acutest cases. It is now over two years since I first introduced the serum treatment of gastric and duodenal ulcer. I have in that time treated over 40 cases of chronic duodenal ulcer by a meat diet, and by administering by the mouth horse serum. In these cases there has been only one failure, in a gentleman who had a jejunal ulcer as well, both ulcers being excised by Mr. Moynihan. All the cases were most intractable to starvation treatment, Lennartz's treatment, or meat diet without serum. They were all diagnosed as instances of duodenal ulcer by experts in different parts of the world, and constituted as rigid a test as possible, several being of over twenty years' standing. In addition I have notes in private letters from medical men of cases treated

¹BRITISH MEDICAL JOURNAL, June 5th, 1909, p. 1392.

in the country by this method, in which success in the majority has been most gratifying. Failures, too, there are, though in some of these the diagnosis has subsequently proved to be wrong, whilst in others the conditions necessary for success have not been complied with. Unqualified failures, unreported, there are sure to be, and I am not without hope that this letter may discover them. The serum treatment is based on the strong probability that ulcer at the point of the duodenum, as of the stomach, is only symptomatic of a yet undiscovered disease, and hence every effort must be made to encourage general nutrition, without which the promotion of local repair is impossible. To encourage general nutrition by full diet is indirectly to encourage the power of local repair. To promote directly local repair it is necessary to combine the peptic and tryptic bodies. This is partly effected by insisting on a proteid diet, which must not be of slop, and partly by administering, at the height of digestion, a serum rich in antipeptic and antitryptic bodies, which combine with the residue of peptic and tryptic bodies not satisfied by the proteid molecules. This at least is the rationale of the proteid and serum treatment, which in practice gives results incomparably better than any medical procedure yet devised. To hope in all cases to ensure rest of stomach and duodenum by starvation is to hope in vain, and merits the reproach of our surgical colleagues. Two years is all too short a time from which to argue as to permanency of benefits derived from the serum treatment, but before utterly condemning the medical treatment of duodenal ulcer it is worth investigating the claims of an absolutely harmless procedure. Without laying undue stress on the fact, it is worth recording that in the last ten months I have been asked to treat no less than 7 cases of gastric and duodenal ulcer in which gastro-enterostomy had completely failed to cure either the ulcer, the hæmorrhage, or the pain. Such failure, however, in no way justifies the wholesale condemnation of a most valuable surgical operation.—I am, etc.,

London, W., May 29th.

E. C. HORT.

"THE DOCTOR AS A VICARIOUS PHILANTHROPIST."

SIR,—I was rather surprised to read Mr. Owen Gwatkin's criticism of Dr. Wishart Kerr's courageous stand against the clamant demand for free medical attendance in cases of accident. Unless a man has abundant private means, those dependent on him must suffer if he gratifies his benevolent and altruistic aspirations by treating without charge any one who rambles, or is brought by sympathetic but parsimonious onlookers, into the surgery for first-aid. A few lessons of the kind Dr. Wishart Kerr administered would be most helpful in educating the public to a due sense of the fact that medical men are not usually rich enough to work for nothing.

I daresay most of us have had demands for the exercise of vicarious philanthropy from certain members of our own profession. Some medical men in large practice do not hesitate to encroach on the leisure of their professional brethren by asking them to do emergency work, which is, in some cases, not even acknowledged by a word of thanks, much less a fee. It is certainly making friendship a profitable thing when it can be used to save the expense of an assistant, and it is difficult if one is friendly with a man to hint that a friend and an assistant are not quite one and the same thing. The end of the matter seems to be that in a "business" world one must be "business" in self-protection, and philanthropy, "vicarious" or otherwise, is a luxury of the rich.—I am, etc.,

Falkirk, June 19th.

GEORGE C. STEWART.

THE PROFESSION, THE ASSOCIATION, AND THE "JOURNAL."

SIR,—I quite agree with Dr. Harry Grey in saying "that about 90 per cent. of members belong to the Association for the sake of the JOURNAL alone." My point is that the converse is also true—that a large proportion of non-members do not belong to the Association because they do not want the JOURNAL. I cannot, however, agree with Dr. Grey that those outside the Association never look at

a medical paper or attend a medical meeting. I think that quite a considerable proportion of non-members do take some medical periodical, and some at least attend medical meetings; and there is also the not inconsiderable point that in a badly-paid profession, the difference between 25s. and, say, 10s. 6d. per annum forcibly appeals to not a few.

I strongly hold that the solidarity of the profession—as evidenced by the absorption into the British Medical Association of practically every medical man practising in these islands—is of infinitely more consequence than any mere increase in the circulation of the JOURNAL. Whether the introduction of a lower-grade subscription would induce any considerable number of non-members to join is a point which the machinery of the Association might well be used to investigate.—I am, etc.,

Rochdale, June 22nd.

J. CUTHBERTSON WALKER.

A MEDICAL ROLL OF HONOUR.

SIR,—You were good enough to publish in the JOURNAL of February 6th a list, compiled by myself, of medical men who remained in London during the Great Plague. I thought that list was complete. I regret to find it was not. Dr. J. A. Nixon, of Bristol, has kindly called my attention to the following notice in the *Intelligencer* for August 7th, 1665, from which it appears that two other names must be added:

Whereas, since the appointment of two Physicians (Dr. Hodges and Sir Thomas Witherley) to administer to the Infected in and about the City, the Plague has so increased, that it is requisite there should be a greater number to take care of the Sick, Be it Known that Doctor Nicholas Austin, a Member of the King's College of Physicians, living in Austin Friars, and Dr. Edward Deantrey, a Member of the same Society living in Broad Street, being two of those Physicians that were presented* by the College to the Right Honourable the Lord Mayor and Court of Aldermen of the City of London for prevention and cure of the Plague, have thought fit, upon principles of Honour and Conscience, to declare that they are ready and willing to attend the said service and to visit all such persons in and about the City and Countries adjacent as shall desire their assistance and directions.

My biographical notes, therefore, published on February 6th, require supplementing by the two following addenda:

Davys, Nicholas, of Austin Friars, was a native of Devonshire, M.D. of the Universities of Leyden and Oxford and Hon. F.R.C.P. I have been unable to recover the dates of his birth and death.

Deantrey, Edward, of Broad Street, was M.D. Oxon. and Hon. F.R.C.P. Further particulars of him are wanting.

—I am, etc.,

London, W., June 14th.

S. D. CLIPPINGDALE.

THEORY AND HYPOTHESIS.

SIR,—It would be a gain if writers of textbooks on medicine would substitute the word "hypothesis" for the ambiguous word "theory," which nobody can accurately define, and which is sometimes used as equivalent to hypothesis, and sometimes as equivalent to a general law or truth, as when we speak of the theory of the tides.

Instead of "theories" as to the etiology of gout, chorea, etc., we should read "hypotheses." For what is a hypothesis? It is a scientific guess. It is any supposition which we make (either with or without actual evidence, or on evidence avowedly insufficient), in order to endeavour to deduce from it conclusions in accordance with facts which are known to be real.

The hypothesis must fit the facts. The facts must not fit the hypothesis. And in order to demonstrate the truth of any particular hypothesis we must show not only that it will explain all the facts, but that no other hypothesis will.—I am, etc.,

June 20th.

M.D.

* Dr. Liversidge, Registrar of the Royal College of Physicians, has been so good as to send me a copy of the Latin minute dealing with this matter. From this minute it appears that the following eight Physicians were originally nominated: "Dr. Joannes Wybræd, Dr. Guis. Conyers, Dr. Humphredus Brooke, Dr. Nathaniel Hodges, Dr. Edwardus Deantrey, Dr. Nicolaus Davys, Dr. Lancelot Harrison, and Dr. Witherley." I have been unable to find evidence that Drs. Wybræd and Lancelot Harrison remained in London.—S. D. C.

Universities and Colleges.

JOINT MATRICULATION BOARD OF THE UNIVERSITIES OF MANCHESTER, LIVERPOOL, LEEDS, AND SHEFFIELD.

AN agreement has now been drawn up for an interchange of matriculation certificates issued by the Joint Board of the Universities of Manchester, Liverpool, Leeds, and Sheffield, and the University of London. In each case there are certain obligatory subjects without which no certificate is issued. In London these are English and mathematics, while under the Joint Board they are either English language or English literature, English history, and mathematics. Each system also requires three other subjects from a list specified in their syllabus. In order to obtain recognition of the certificate by both bodies, these three optional subjects must be chosen from the following list: Greek, Latin, French, German, mechanics, chemistry, geography. The Joint Board further requires that one of the subjects shall be a language. The London University requires that one of the three subjects must be either Latin or a science, and that if Latin be not taken, one of the other subjects must be another language from the list, and further, that the certificate should state that the candidate has passed in "unprepared translation in lieu of set books." These conditions are what each body requires from its own candidates.

THE VICTORIA UNIVERSITY OF MANCHESTER.

Chemistry Department.

MR. A. LAPWORTH, D.Sc., has been appointed a Senior Lecturer in Chemistry and Assistant Director of the Inorganic Laboratories. He has also been elected to a Schunck Fellowship, part of the duties of which will be to conduct and supervise research in the Schunck laboratories. Mr. Lapworth is at present head of the chemical department of the Goldsmiths' Institute, London, and is the son of Dr. Lapworth, Professor of Geology in the University of Birmingham.

Visit of the King.

At a meeting of the University Council the Vice-Chancellor said that it was expected that the King would make a short stop at the university on the occasion of his visit to Manchester to open the New Infirmary on July 6th, and an address to be presented was approved.

Popular Lectures.

Arrangements have been made for a series of free popular lectures on Monday evenings during the coming session, and in addition a series of museum lectures will be given by Professors Flinders Petrie, Boyd Dawkins, Hickson, and Weiss.

UNIVERSITY OF EDINBURGH.

Medical Education.

At a meeting of the Students' Representative Council on June 17th it was agreed:

That the Senatus be petitioned to appoint a committee to institute an inquiry into the present state and methods of teaching in the Medical Faculty, with a view to increasing, if necessary, the amount of time spent upon practical training, and that a copy of this resolution be sent to the Dean and professors of the Medical Faculty.

The Services.

INDIAN MEDICAL SERVICE.

STUDY LEAVE.

THE *Gazette of India* of May 21st contains the following: "Paragraphs 3 and 8 of the regulations regarding the grant of study leave to officers of the Indian Medical Service, as published in the Department of Military Supply, Notification No. 16 of 1907, are reconstructed as follows: Study leave may be taken at any time, but will not be granted more than twice in the course of an officer's service. This restriction does not, however, apply to an officer who has part of his furlough converted into study leave under Rule 8. Officers on furlough, or other leave, who wish to have part of it converted into study leave should address the Under Secretary of State, India Office, and should attach a statement showing how they propose to spend the study leave. Similarly officers on furlough or other leave who desire to have it extended for the purpose of study should address the Under Secretary of State, but, in addition to the statement of the proposed study, they must support their applications with documentary evidence of their having obtained the approval of the authorities concerned in India to their applying for an extension of leave."

THE French Association for the Advancement of Science will hold its annual meeting this year at Lille from August 2nd to the 7th, under the presidency of Professor Landouzy, Dean of the Paris Faculty of Medicine. The Section of Medicine will be presided over by Professor H. Roger of Paris. The following questions are proposed for discussion: (1) The new methods of diagnosis and treatment of tuberculosis; (2) cerebro-spinal meningitis; (3) pathological physiology and pathology of the digestive canal.

Medico-Legal.

WORKMEN'S COMPENSATION CASES.

Chronic Bronchitis.

In a case heard in the Court of Appeal on May 26th, a man whose knee had been injured by the fall of a stone was compelled to crawl home as best he could. He was consequently exposed to the weather for three hours in December. As a result he suffered from double pneumonia which was followed by chronic bronchitis, and this prevented him from working. A county court judge refused compensation on the ground that the incapacity to work "was not the natural or probable result of the injuries." On appeal it was pointed out that, according to the medical evidence, the blow to the knee produced a shock which reduced vitality, and it was the exposure while his vitality was impaired which did the mischief. For the employers it was contended that the county court judge had found and was justified in finding, that the man's condition was not the proximate cause of the injury. The Court of Appeal held that there was evidence worthy of consideration as to whether the man's weak condition was due to the accident. The real question was whether the man's condition was a result of the accident in this sense—that it was occasioned by the debilitated condition of the man immediately after the accident. The case was sent back to the county court judge for consideration in the light of this finding.

"Strained Heart."

In a case heard at Wolverhampton on May 25th, a brewer's labourer claimed compensation for strained heart, which rendered him incapable. It appeared that he had been in the employment of a firm of brewers for twenty-three years. On March 11th, 1908, he collapsed while carrying a heavy bag. He had previously had pains over his heart. A month later, Dr. Grout told him his heart was strained. His sick club paid him until September, when the firm paid him 5s. a week until February, 1909. Dr. Grout, in his evidence, said that the cardiac weakness was probably due to lifting heavy weights, but he could not say it was entirely due to what happened on March 11th. The county court judge held that the strain was due to the nature of the employment, not to an accident, and dismissed the claim.

Seamen and Industrial Diseases.

One of the anomalies of the Act was brought to light in a case which was heard in the Court of Appeal on May 25th. The applicant was a boatswain who had been employed as painter-mixer on board ship. Owing to his employment he suffered from lead poisoning, which disabled him from work. He claimed compensation, as lead poisoning is one of the industrial diseases for which employers are liable. It was pointed out, however, that compensation for industrial disease is only payable (1) on the certificate of the district certifying surgeon appointed for the district in which the workman is working; or (2) where a workman is suspended in accordance with special rules under the Factory and Workshop Act, 1901; or (3) where death ensues. The Court held that, as there can be no certifying surgeon in the case of a seaman at sea, there could be no claim in respect of an industrial disease suffered by a seaman.

"Arising out of the Employment."

The Court of Appeal on May 26th upheld a decision of the judge of the Gloucester County Court, who, sitting as arbitrator, refused compensation to a domestic servant injured in the following circumstances: She was employed as a lady's maid and sewing maid, and was sewing one hot night last June with the window open. A cockchafer, attracted probably by an electric light in the room, flew in at the window. To frighten it away, she threw up her head, and struck herself on the right eye with the knuckle of her thumb. The result was the formation of a cataract, which, although removed by an operation, left her with permanently defective vision. In giving judgement, the Master of the Rolls remarked that what the court was really asked to do was to remove from the Workmen's Compensation Act the words "arising out of the employment," or to treat them as of no account. The Court could not depart from its invariable rule, which was to hold that it was not enough for an applicant to say that the accident could not have happened if he had not been in that particular place. The applicant must show that the accident arose because of something he was doing in the course of his work or because his work placed him in a position of peculiar danger. Unless that was established, the applicant must fail, because the accident did not arise out of the employment. In this case the maid was not placed in any position of special danger. The intrusion of a cockchafer into a lighted room through a window was a thing that might happen to anybody, and it seemed impossible to say that the fright which led to the applicant putting her thumb into her eye was something caused by her employment. The other two judges concurred, and the appeal was dismissed.

Aortic Aneurysm.

VERITAS.—We are inclined to the opinion that it is not possible to state with any approach to accuracy the length of time an aortic aneurysm has existed, nor is it possible to tell from a specimen the age of the pathological changes. The possibilities appear to be, from the evidence before us, that the man at the time of injury was the subject of atheromatous disease and that he had an aneurysm which up to that time did not cause incapacitating or disabling symptoms. A severe strain or effort occurring in a person suffering from atheromatous

degeneration of the aorta may produce damage there, but in the case as reported the strain can hardly be considered to have been severe, so that the presumption is in favour of the pre-existence of some form of aneurysmal dilatation. In a case of aneurysm, an effort may cause the dislodgement of a clot, but embolism may be merely a coincidental circumstance which would have occurred without the least relation to the trauma. It must be admitted that the displacement of a clot would be more likely to follow injury or effort, and it is quite clear that this patient became totally incapacitated immediately after an occurrence which might be regarded as an effort or strain. Whether or not the occurrence mentioned is an accident arising out of or in the course of the man's employment, is a question of law, and the opinion of a solicitor should be sought; he will advise if the evidence is of such a character to be capable of presentation to the county court judge for decision.

CORONER AND MEDICAL WITNESS.

MEMBER has sent us an account of an inquest recently held near Trowbridge concerning the death of a newly-born child, unidentified and found dead in a ditch. Our correspondent, the medical witness, after making a very careful *post-mortem* examination, came to the conclusion the child was born alive, had fully breathed, and had a complete and separate existence from the mother, the lungs having been fully inflated with air; and that it had died from asphyxia caused by external constriction round the neck. There was a distinct pressure mark round the neck 3 in. wide, and at one place deeper marks, as if knots had been tied, and he concluded that either tape or some such material must have been used. He said, in answer to the coroner, that he did not think that the umbilical cord could have caused such a mark as he saw. Other questions were put to him rather disparaging to his evidence. Ultimately the inquest was adjourned to give the police time to make further inquiries.

At the adjourned inquiry, and despite the clear and distinct evidence of our correspondent, the coroner, who is a lawyer, summed up, and suggested that the jury could return one of three verdicts: First, of accidental death, by the cord getting round the neck at the time of birth; secondly, they could say "Found dead, with insufficient evidence to show the cause"; or, thirdly, they might return a verdict of wilful murder against some person or persons unknown, if they believed the doctor's evidence was sufficient, but he thought it was hardly conclusive.

The jury then retired, and consulted in private for some time, and brought in a unanimous verdict that the deceased was wilfully murdered by some person or persons unknown.

We agree with our correspondent that had the coroner been a medical man, he would have more fully appreciated the medical evidence; but, notwithstanding, "twelve good men and true" evidently fully believed the medical evidence given, and returned their verdict in accordance with it. We think now that the medical witness should rest satisfied.

Obituary.

EDWARD CHARLES CRIPPS,

EX-PRESIDENT GLOUCESTERSHIRE BRANCH, BRITISH MEDICAL ASSOCIATION.

MR. EDWARD CHARLES CRIPPS, of Cirencester, died recently after an illness which had lasted nearly two years, and necessitated more than one operation. The results of the latest seemed to promise entire recovery, and in that belief he had gone to Bournemouth to complete his convalescence, but dangerous symptoms reappeared, and he was removed to his home by motor ambulance, reaching it only two days before his death. His long illness had in nowise lessened the number of his friends, and the news that it had ended fatally was received with widespread regret. It was not quite unexpected, of course, by those in direct touch with Cirencester, but among his more distant friends it has caused much surprise; for Charles Cripps, as he was locally called, in contradistinction to the Edward Cripps who preceded him, had only reached the age of 54, and seemed an unusually healthy man, much more likely to survive than to predecease his compere and coevals.

Mr. Charles Cripps came of an old Gloucestershire family long connected with Cirencester. His father practised in that town before him, his grandfather held a vicarage in the neighbourhood, and his great-grandfather represented the locality in Parliament for the long period of fifty years. His early education he received at Guilford, and on its completion joined St. Bartholomew's Hospital. There he forthwith became "Ox Cripps" to all and sundry, and by many of his friends would not have been recognized by any other title to the end of his life. It was a tribute alike to his physical proportions and to his sterling

amiable character, for he possessed to the full those qualities of cheeriness, geniality, and coolness on all occasions, which are commonly supposed to accompany great physical strength and size. After receiving the diplomas of the two Royal Colleges in London in 1877, he served the hospital for a year as House-Surgeon, and then became Medical Officer to the Central London Sick Asylum at Highgate, an early example of the modern Poor Law infirmary, and at that time a show place among such institutions. This post he held for several years; then came a few voyages to the East as a medical officer in the P. and O. Steamship service; and finally his settlement in Cirencester in succession to his father. His life there was one both of professional and social success. A thoroughly sound surgeon and medical adviser, he was held in great professional esteem both among the general population and among his colleagues, his skill as an anaesthetist being especially esteemed by the latter. He was also a tower of strength in support of all outdoor occupations among both the younger folk and his older neighbours. An all-round athlete himself, he did much both for cricket and football in the town, and popularized swimming, in which art he was specially accomplished. It was he, too, who laid out the Sabberton Golf Course, and who founded what is now the Cirencester Golf Club. He was not, however, only an outdoor man. He possessed considerable musical talents, and was often called upon to use his attractive voice at social functions and on behalf of local charities; and he was a prominent Mason, a Past Master of the Cotswold Lodge, and Past Provincial Director of Ceremonies for Gloucestershire. Even from a mere sense of *esprit de corps* such a man as Charles Cripps was bound to become a member of the British Medical Association, and in Gloucestershire he did much to promote and consolidate its interests, both by leading other men to join this body and by taking an active part in its affairs. He was a ready and clear speaker whenever occasion required, and served a term of office as president of the Branch, and remained a member of the Branch Council up to the time of his death. Mr. Charles Cripps was married, and is survived by his wife, one of the Elliots of Andover.

FREDERICK NUTCOMBE HUME, M.R.C.S., L.R.C.P.,

MEDICAL SUPERINTENDENT NORTH-WESTERN FEVER HOSPITAL, HAMSTEAD.

WE regret to record the death of Mr. F. N. Hume, which occurred at the age of 58, at his residence in Hampstead, on June 14th. His death was very sudden. He appeared to be in his usual health on Sunday, but in the night was seized with an acute pain in his chest, and was seen by one of the assistant medical officers. He remained in bed on Monday morning, and sent for his friend, Dr. W. F. Corfield, who saw him about 2 o'clock, when he seemed quite himself, but a few minutes after was seized with another attack of pain, apparently angina pectoris, and died immediately.

Mr. Hume was the third son of the late Rev. C. N. Hume, Rector of Meonstoke, Hants. He was educated at Marlborough School, and subsequently entered Wadham College, Oxford, in order to read for classical honours. After some two years, being strongly attracted to medical study, he joined the medical school of St. Thomas's Hospital, obtained the diploma of M.R.C.S. in 1876 and that of L.R.C.P. at a later date. During this student period he held the appointment of Clinical Assistant at the Victoria Park Chest Hospital. In 1876 he was appointed as one of the Surgeons to the National Aid Society's Ambulance in the Servo-Turkish War, and in the following year joined the Stafford House Ambulance in the war between Turkey and Russia. In 1878 he served for a time as Assistant Medical Officer at the Metropolitan Asylums Board's South-Eastern Hospital. He practised subsequently in Kensington for some years, and in 1885 again served with the National Aid Society in the Servo-Bulgarian War, and afterwards as Director of the English Hospital at Belgrade. He received the Takova, Medjidieh, and St. Sava Orders, as well as Turkish and Servian war medals.

In 1886 he re-entered the service of the Metropolitan Asylums Board as assistant medical officer at the South-Eastern Hospital, and was successively superintendent of

the Northern Hospital at Winchmore Hill, and of the North-Western Hospital at Hampstead, where he remained till his death.

On the formation of the Territorial Force last year Mr. Hume was the first to be offered the command of one of the newly-established sanitary companies, that attached to the 2nd London Division. He was gazetted Major in the R.A.M.C. Territorial Force last July, and since that time has worked hard to get his unit to the state of efficiency it has attained. The establishment of officers was only completed the week before his death, and the N.C.O.'s and men were almost up to the full establishment. His place will be difficult to fill.

His interest in public medicine was keen and unflagging. At the Northern Hospital, where there were large numbers of diphtheria cases among the convalescents from scarlatina, he was one of the first to test on a large scale the effects of the antitoxin treatment in the early stages of diphtheria. His reports on this experience are of much value. At the North-Western Fever Hospital he was appointed as one of the clinical instructors to London students. His teaching there was clear and practical, and greatly enjoyed both by himself and his pupils. He brought to his medical work in a high degree the essential qualities of a genuinely scientific mind, untiring energy, a deeply sympathetic nature, and a fine conscientiousness. His administration was able, and he won the warm regard and respect of all whom he served or who served him, whether in hospital or military work.

His many sorrowing friends can testify to his charming social qualities, and not least to the bright intelligence and kindly humour which inspired his conversation, and the high courage and promptitude which marked his actions.

He was buried at the Hampstead Cemetery on June 18th, the funeral being attended by his family and by many of the hospital staff as well as representatives of the Metropolitan Asylums Board, the Local Government Board, and the 2nd London Division of the Territorial Force, including all the officers of his unit; the coffin was carried by eight privates. He leaves a wife and two young sons.

Dr. PLUMBE, who had practised for thirty-one years at Maidenhead, was found dead in his bedchamber on the morning of June 7th. He had attended as usual to his professional work the day before, and seemed to be well and strong when he retired to rest, but he had suffered from an attack of syncope three years earlier, and it was then discovered that he was already the subject of heart disease. His father died suddenly in December, 1876, at the age of 52, and Dr. Samuel Plumbe himself was only 56 at the date of his decease. He died unmarried. Dr. Samuel T. Plumbe was the son of Dr. Samuel Alderson Plumbe, who settled in Maidenhead in 1852. He studied at St. Bartholomew's Hospital. He graduated M.B.Lond., and obtained the diploma of M.R.C.S. and L.S.A. in 1877, and took the degree of M.D.Lond. in 1882. He held for a time after his first qualification the appointment of House-Surgeon to the Kent and Canterbury Hospital. In 1878 he joined his deceased father's partner, Dr. Edwin Cuthbert Montgomery, in practice. Dr. Plumbe was widely and deservedly popular, being skilful, prompt, punctual, and extremely humane. His funeral, which took place at Maidenhead Cemetery on June 10th, was very largely attended, and the assemblage of persons representative of all classes was a striking testimony to the affection and esteem in which he was held throughout the town and district.

AFTER a seizure of double pneumonia on May 27th Dr. J. H. WILLIAMS passed away at his old home, Llanidloes, North Wales. The news occasioned universal sorrow at Aberavon. He was born in 1857, and was the son of the late Thomas Williams of Llanidloes. He received his medical education at the London Hospital, and about fifteen years ago settled in Aberavon, where he quickly became popular through his genial and kindly nature. His popularity may be judged from the fact that a couple of years after his advent he contested a seat on the town council, and was returned at the head of the poll. He was soon added to the Commission of the Peace for the borough of Aberavon. After being again returned at the head of the poll he was made an alderman, and in

the year 1902 occupied the mayoral chair of the borough. He was afterwards put on the Commission of the Peace for the county of Glamorgan. He represented the council on the Port Talbot Pilotage Board and the Port Sanitary Authority, and was a Freemason for many years. He was Medical Officer for Port Talbot Docks and Railway; Surgeon to the English Celluloid Company; Surgeon to the Whitworth Collieries; Medical Inspector of Seamen; Surgeon to various works and insurance societies. He leaves a widow and two young daughters.

Public Health

AND

POOR LAW MEDICAL SERVICES.

THE ADULTERATION OF RICE.

THE Local Government Board has issued a report (Reports to the Local Government Board on Public Health and Medical Subjects. New series. No. 4) by Dr. J. M. Hamill on "facing" and other methods of preparing rice for sale by the use of adulterants. It has been ascertained by the authorities that rice millers are generally not content with the appearance given to rice by ordinary mechanical methods of treatment, but endeavour to improve upon it in various ways by the use of extraneous substances during or subsequent to the milling. Talc or kindred substances are used to impart a high polish or glaze to the grain; pigments of various kinds are sometimes brought into requisition in order to modify its colour; and oil may be employed to increase its translucency. The use of talc (French chalk) or stearate in the form of a fine powder is particularly common. It is generally mixed with glucose, glycerine, and starch paste before it is applied to the rice, and sometimes also with mineral oil. This glazing mixture forms an exceedingly thin coating on each grain and ensures the adherence of talc in sufficient quantity to give the required degree of lustre. Rice has normally a creamy white colour; but a demand has been artificially created for a rice of dead whiteness, and this is attained by the addition of blue pigments, either mineral or organic, during the milling process. Ultramarine is most commonly used, but Prussian blue is also employed, or at least was used until quite recently. Amongst the organic pigments indigo has been used, but at the present time the aniline blues of one kind or another are in vogue. Rice in the natural condition varies considerably as regards its translucency, some varieties being very opaque. This opacity can be greatly modified by treatment with oil, whereby the grain obtains a dull, pearly translucency which has been found to prove attractive to many rice consumers. For this purpose a vegetable oil, such as arachis oil, is used to some extent; but as oils of this nature have the disadvantage of easily becoming rancid, a mineral oil or petroleum is more generally preferred. In discussing these commercial methods of treating rice as a possible danger to health, Dr. Hamill admits that minute amounts of talc, colouring matter, or oil may not do any harm; but he points out that the presence in this food of comparatively large quantities (such as 1 to 2 per cent.) of insoluble and possibly irritating mineral matter might in some circumstances be deleterious, particularly to infants or invalids.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Dudley.—The medical officer for Dudley (Dr. J. W. Wilkinson) in his annual report states that the death-rate for 1908 was 15.23 per thousand of the estimated population, and that it is the lowest rate ever recorded in the borough. The death-rate from the seven principal zymotic diseases was only 1.0 per thousand. The infantile mortality-rate again showed a marked improvement upon previous years. The birth-rate was 30.25, and showed a slight falling off as compared with that of 1907, but was not, however, so low as in 1906, when it was 29.73. An enormous amount of work had recently been carried out by the chief sanitary inspector in getting houses connected with the deep drainage system, and it had been fraught with much difficulty, owing to the expense entailed upon property owners. During the year 520 houses have been provided with proper drainage, and the water carriage system applied to 823. The medical officer speaks very highly of the admirable work which is being done in this direction to improve the health of the borough.

Herefordshire Combined Districts.—The report of Dr. Herbert Jones, medical officer of the Bromyard, Dore, Hereford, Ledbury, Leominster, and Weobley rural districts, relates to a scattered and slowly decreasing population, estimated to number 51,168 persons in the middle of last year. The birth-rate per 1,000 of population was only 21.5, as against 26.2 in rural districts England and Wales as a whole. Calculated, however, on the number of women between the ages of 15 and 45, the difference between the Herefordshire and the general rate would appear to be trifling. The death-rate was 15 per 1,000; it was lowest at Bromyard (10.7), and highest at Weobley (14.6). The infant mortality-rate was only 62 per 1,000 registered births. Dr. Jones makes no comment on this fact, which, however, is remarkable testimony to the value of the work done by him.

We gave some account of it last year, when the infant mortality was likewise much lower than the average figure for rural England and Wales. The secret seems to lie in the extent to which village nurses are used and the care which is taken by Dr. Jones to see that they are properly instructed and their work duly supervised. It is noteworthy likewise that the death-rate amongst illegitimate children in this area was not only exceedingly low in itself—namely, 57 per 1,000—but lower than the death-rate amongst legitimate children, whereas all over the country it tends to be both actually and relatively very high. The number of such births was also greater in proportion to the population than is usual throughout the country, and this fact, taken in connexion with the low death-rate amongst illegitimate children, perhaps represents a local attitude towards the subject which renders it comparatively easy for unmarried mothers to pay an adequate amount of attention to their children. The pithitis death-rate averaged 1.07 per 1,000, which is somewhat less than that of rural England and Wales in 1907, but considerably higher than the rate for the previous ten years in this particular district. The cancer-rate was 1.55, which again is much higher than the record of the previous ten years. Indeed, nearly 1 in 10 of all the deaths in the district seems to have been due to this disease. The same volume also includes particulars concerning the Bromyard Urban District, of which Dr. Jones is likewise medical officer. It has a population of 17,704, and its corrected death-rate 16.7, or 3.7 per 1,000 higher than in the combined rural area surrounding it. The only circumstances which would seem to explain this difference is the high rate of persons per acre in the combined rural area, which is 0.15 per acre, and in the Bromsford Urban District nearly 9.

Merton Urban District.—Merton is a rapidly increasing district, which until the end of 1907 was included within the area of administration of the Croydon Rural District Council. In 1901 it had a population of 4,500 persons, and in the middle of 1908 this had increased to 12,550. The birth-rate during the year was 28.5 per 1,000, the death-rate 7.9 per 1,000, and the infantile mortality-rate equal to 48 per 1,000 births. The rural isolation hospital is still used by the newly formed urban district, and in 1908 as many as 85 per cent. of the cases of diphtheria were removed there, while only 3 of the 18 scarlet fever patients and only 1 of the 4 typhoid patients were nursed at home. The importance of this can be better appreciated when we learn that nearly all the houses in the district are let on weekly rentals. The medical officer of health (Dr. D. A. Bellios) has drawn up a very useful pamphlet, which was delivered at every house in the locality, giving appropriate advice for the prevention of summer diarrhoea among young children. In 1908 only five deaths were registered as due to this disease.

Borough of Bath.—The population of Bath at the census of 1901 was 49,839, or some 2,000 less than the number recorded at the previous census. Estimated by the Registrar-General's method, the population of the city at the middle of 1908 would be 48,751, but Dr. Symons is of opinion that there may have been an increase since the last census and not a decrease. For statistical purposes, therefore, he estimates the population at 50,000, or the same number as in the three previous years. This cannot be considered satisfactory and emphasizes the importance of enumeration more frequently than every ten years. The death-rate during 1908 was 15 per 1,000 of the population, and the infantile mortality-rate equal to 87 per 1,000 births. The birth-rate was 19.5 per 1,000 of the population at all ages, compared with 26.5 per 1,000 in England and Wales. This very low birth-rate is more apparent than real, for, calculated as it should be, and as Dr. Symons has, it is equal to 207 per 1,000 married women between the ages of 15 and 45 years. In 1907 the ratio in the whole of England and Wales was 215.6. It is a pity that more medical officers of health do not adopt this method of calculating the legitimate birth-rate. There are 23 private slaughterhouses in Bath, 26 of which were established before 1847. It is satisfactory to find that 3 slaughterhouses which were of a very bad type have been acquired by the corporation. A health resort with the reputation of Bath ought to have a public abattoir, for the difficulties attending the proper supervision of the 23 private slaughterhouses must be almost insurmountable.

RESIGNATION OF MEMBERS OF BOARDS OF GUARDIANS.

LIBRA.—There is no line on resigning the office of Poor Law guardian. The question of resignation is a matter solely to be dealt with by the Local Government Board, and any application from a guardian to resign has to be sent to that Board by the applicant, and reasons given for wishing to resign office as guardian. It is not essential for a guardian to resign before becoming a candidate for a paid office under his board, but in the event of his being elected to any such office he would be disqualified from serving as a guardian.

BY LAWS OF LOCAL AUTHORITIES.

5825.—Section 37 of the Local Government Act, 1894, reads as follows: "Any laws, orders, regulations, and resolutions of any authority whose powers and duties are transferred by this Act to any council, as are in force at the time of the transfer, shall, so far as they relate to or are in pursuance of the powers and duties transferred, continue in force as if made by that council, and may be revoked or altered accordingly."

Letters, Notes, and Answers.

BRITISH MEDICAL ASSOCIATION AND BRITISH MEDICAL JOURNAL.

The offices of the British Medical Association and of the BRITISH MEDICAL JOURNAL are at 429, Strand, London.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, London, W.C.; those concerning business matters, advertisements, non-delivery of the JOURNAL, etc., should be addressed to the Office, 429, Strand, London, W.C.

TELEGRAPHIC ADDRESS.—The telegraphic address of the EDITOR of the BRITISH MEDICAL JOURNAL is *Articulate, London*. The telegraphic address of the BRITISH MEDICAL JOURNAL is *Articulate, London*.

TELEPHONE (National).—2531, Gervard, EDITOR, BRITISH MEDICAL JOURNAL. 2534, Gervard, BRITISH MEDICAL ASSOCIATION.

2534, Gervard, MEDICAL SECRETARY.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate with the Office, 429, Strand, W.C., on receipt of proof.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look at the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

In order to avoid delay, it is particularly requested that ALL letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not at his private house.

✉ Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

HYPERTRICHOSIS asks for the best treatment for temporary alleviation and permanent cure of trichosis, abundant and downy, on a lady's upper lip.

PRACTICE IN NEW ZEALAND.

L. J. asks for information as to the best means of obtaining a good and reliable partnership practice in New Zealand, with proper facilities for a thorough investigation.

DISTURBED NIGHTS.

NIGHT BIRD writes: When called up at eight I often find I cannot get to sleep again and am done up next day. Can any one suggest the best stimulant (non-alcoholic) to take on these occasions to induce sleep? It must be a common experience with others.

CANCER OF BLADDER.

DR. J. BURTON CLELAND (Chief Secretary's Department, Bureau of Microbiology, Sydney) writes: I am anxious to find out a reference to a permanent disease (7 prostatic) occurring in the urinary bladder of workers in one of the coal-tar dye industries, fuchsin workers. I believe it may be possibly, however, in indigo workers. I am unable to come across it in the literature available in Sydney.

INCOME TAX.

PERPLEXED has been asked by the surveyor of taxes to furnish particulars of his takings and working expenses for the years 1907 and 1908. As his income tax for those years has been paid and the return for this year sent in, he wishes to know whether he is bound to go to the trouble of furnishing the particulars.

*. The object of the surveyor of taxes in applying for this information is doubtless to verify the amount returned as to the liability for the current year. This return should have been made on the average profits of the three years 1906, 1907, and 1908, and from the fact that the request does not extend to the profits of 1906 it is assumed that the figures for that year have previously been furnished, or that the practice is a new one. Our correspondent is not bound to furnish the information at the request of the surveyor, but it will probably save him trouble in the long run to do so, inasmuch as the surveyor's object is presumably to ensure that a correct assessment shall be made. It is possible that non-compliance with the request may result in an estimated assessment being made by the Income Tax Commissioners, in which case the full details will be insisted on in connexion with the consequent appeal.

A. S. inquires as to the income tax liability in regard to quarterly instalments paid in respect of the purchase price of a practice.

*. The quarterly instalments in such a case do not represent income to the recipient any more than would the payment of the whole purchase price in one sum. The instalments should accordingly not be returned by the recipient for assessment to income tax. So far as the purchaser is concerned, the quarterly instalments must be regarded entirely as capital outlay, and no deduction should be made on account of them from his receipts in arriving at the profits to be returned for income tax purposes.

ANSWERS.

HOSPITAL WALLS AND FLOORS.

DR. W. B. PARSONS (London) writes, in reply to "Savage" (p. 1520), to recommend Paripan, the South African agents for which are Messrs. Fraser and Chalmers, Ltd., Johannesburg. It presents, he says, a smooth and highly-glassed surface, is durable, and can be washed with ordinary antiseptics without deterioration.

STUDY OF EYE DISEASES.

POST-GRADUATE would probably find the best place for studying eye diseases for the F.R.C.S. (Edin.) would be the special eye hospitals of London or Edinburgh. Of the Continental schools, for one who speaks German, Vienna or Freiburg, and one who speaks French, Paris or Brussels are probably the best for the purpose. Freiburg and Brussels are fairly cheap to live in, and the teaching of Axenfeld at Freiburg is excellent.

BRONCHOSCOPY.

DR. WILLIAM HILL (London) writes: Dr. Charles W. Chapman will find the information he requires as to the value of the bronchoscope in the diagnosis of intrathoracic tumours in Chevalier Jackson's monograph on *Tracheobronchoscopy, Oesophagoscopy, etc.* (St. Louis, 1907), in which there is a bibliography of 358 references. He might also consult the article on bronchoscopy in *Allbutt's System of Medicine*, vol. iv, part 2.

* Dr. Jackson's book was reviewed in the JOURNAL, 1903, vol. i, p. 1236.

STALE ASPARAGUS.

CAPTAIN E. BLAKE KNOX, M.D., D.P.H., R.A.M.C., writes: I was much interested in "A.L.'s" query about gastro-intestinal irritation due to eating stale asparagus (p. 1520 of June 19th) as I have had exactly the same personal experience. In two cases which I have recently seen severe diarrhoea occurred in each and vomiting in one; the symptoms closely resembled ptomaine poisoning and I made a very careful investigation and analysis of the food taken prior to the illness. Pieces of blackened asparagus fibres covered with stringy mucus were passed in the stools, and these, no doubt, were the causal agent, as all other food taken was proved to be absolutely above suspicion. The asparagus was described as slightly flabby before being cooked. I have seen similar cases occurring from eating stale spinach. Perhaps the method of applying liquid manure to these vegetables has something to do with the formation of poisonous bodies when they get stale. I believe asparagus, like sea-kale, is often grown in beds covered by manure mixed with ash-pit refuse, which from its heating properties forces growth. As the contents of many ash-pits contain putrifying animal matter, the presence of ptomaines on the surface of these vegetables can be easily accounted for.

LETTERS, NOTES, ETC.

ANIMAL PARASITES.

PROFESSOR M. BRAUN and Dr. M. LUHE (Königsberg) write: In your issue of May 8th you publish a review of Braun and Luhe's *Leitfaden zur Untersuchung der tierischen Parasiten des Menschen und der Haustiere*, in which your reviewer expresses himself as follows: "A glance at the general style, printing, diagrams, and text of the work shows at once that it is based upon, or might even be termed, a synopsis of Braun's well-known work." Then he censures one of the authors for "considerable changes introduced into the old and time-honoured classification of the protozoa." It is rather hard to understand how this both can be true. Indeed, a glance at the table of contents shows at once that Braun's former work and the work under discussion are quite different from each other, the one detailing the parasites of man and their life histories, the other the methods of obtaining, preparing, preserving, and examining parasitic material. Both intend to supplement each other. No less than 23 of the 100 illustrations of the *Leitfaden* are wanting in Braun's former work, and the readers will judge whether the new work is really a "synopsis" of the former or a "practical companion" to it, as we may describe it. Moreover, it is not possible to accept your statement that considerable changes are introduced into the classification of the parasites. The most important of these so-called changes, the inclusion of the haemoflagellates and haemosporidies in a single order, is introduced by Hartmann two years ago, and the paragraph of the work under discussion dealing with this question is concluded as follows: "Although this basis of classification is not, as yet, accepted by all authors, it is expedient to the present purpose to class the blood parasites together, more particularly as the method of examination is the same in both cases." It is to be regretted that the "glance" which your reviewer bestowed upon the text of this work was of so cursory a nature, and that he should have so wholly mistaken both its intention and its scope.

* It is not unusual for authors, if a book be unfavourably criticized, to suggest that the reviewer has not read or has only glanced at it, but we cannot accept the insinuation in this case. The resemblance between the volume under notice and Braun's well-known work in style and text is close, and we calculate that 73 of the 100 diagrams in the new book are the same. Neither can we accept our correspondents' opinion as to the classification adopted; the fact that "the

method of examination is the same in both cases," ought not, in our opinion, to be made the basis of classification.

HUNGER PAIN OF DUODENAL ULCER.

O. I. writes: I have followed the discussion on this subject with unusual interest, having been myself a sufferer at intervals for the last four years. About three years ago I consulted a physician, who diagnosed "hyperacidity." I had grave doubts as to the correctness of his diagnosis, and from more than one article which I had read in the JOURNAL about that date on the subject of duodenal ulcer I was convinced that such was the cause of my symptoms.

As a small boy I had suffered occasionally from heartburn, accompanied by acid eructations. Since then, till about four years ago, I had no stomach troubles. About the date mentioned I began to feel pain in the region of the stomach, which I could only describe as cramp. It came in paroxysms. Beginning with the slightest degree of discomfort, it steadily increased in intensity until it reached its height, and then as steadily decreased in severity till it disappeared, the whole time occupied being about 10 to 15 seconds. After an interval of about half a minute another paroxysm occurred. These continued regularly for about an hour. Each paroxysm was rather more severe than the preceding, until a certain stage was reached, and then they began to taper off gradually until they entirely ceased. These attacks came at first only about 9 or 10 p.m.

A mouthful of undiluted whisky caused eructations, and was speedily followed by complete relief at first, but soon failed to act with the same efficiency, and was consequently stopped. By and by these symptoms began to occur during the day, but almost invariably several hours after a meal, and the taking of food always brought relief. At a later period the trouble only occurred during the night. At the height of an attack exceedingly tough mucus was rapidly secreted from the fauces—so tough, indeed, that it could not be swallowed, although there was a constant desire to do so. It had to be hawked up vigorously, and on spitting it out it clung to the lips, forming a rope of mucus 3 ft. or 4 ft. long. This is an invariable accompaniment of these attacks, and on which I have not seen mentioned by any of your correspondents.

When an attack was unusually severe, it usually terminated rapidly with pyrosis. The pain was not on any occasion what one might call acute.

Diet did not appear to have any marked influence in bringing on an attack. The appetite has remained good throughout. In corroboration of my own diagnosis I once observed a loose motion which had every appearance of melæna.

With regard to the cure of this condition in my own case I have some doubts. During the last eighteen months I have had only two periods of a very few days each, of any degree of severity, although I have occasional twinges to remind me of the past.

Regarding the treatment I have adopted, it may be of interest. After the whisky failed to give relief, I tried fasting and various remedies without much success till I used liquor potassæ in ss to xx , with the same quantity of tinct. of iron in water, taken whenever the pain threatened, and continued for a few days before meals. After two or three days this treatment has never failed to bring about complete relief which has continued for considerable periods of time. I may say that I was led to adopt the above treatment on the assumption of hyperacidity.

Some of your correspondents have referred to recurrences after apparent cure. Has anyone observed anything approaching seasonal periodicity? On reflection, it appears to me that my attacks have usually occurred during the summer months.

A WARNING.

OUR attention has been called to a case in which a medical attendant on a family was asked by one of the family members to sign a declaration in order that he might obtain a Foreign Office passport. This was done without the practitioner making any special inquiries, since he knew the family well, and had no reason to suspect the individual member making the application. The passport was duly granted. Our correspondent recently received a letter from the Foreign Office reprimanding him for signing the application and reciting a series of convictions against the individual in question. The passport was issued on the basis of various terms of imprisonment. We therefore venture to warn medical practitioners against signing any forms for patients without making full inquiry.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.

	£	s.	d.
Eight lines and under	0	4
Each additional line	0	6
A whole column	2	4
A page	8	0

An average line contains six words.

All remittances by Post Office Orders must be made payable to the British Medical Association at the General Post Office, London. No responsibility will be accepted for any such remittance not so safeguarded.

Advertisements should be delivered, addressed to the Manager, 425, Strand, London, not later than the first post on Wednesday morning preceding publication, and, if not paid for at the time, should be accompanied by a reference.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

1. Duodenal Ulcer in the First Decade.

L. KUTTNER (*Berl. klin. Woch.*, November 9th, 1908) records the details of 2 cases of duodenal ulcer in children. The first case was that of an infant of some 30 days, who suffered from diarrhoea and vomiting from the seventh day of life. On the ninth day the stools were stained with blood, and on the thirtieth day a profuse bleeding took place, which led to death within a short time. The only signs made out during life were meteorism, enlargement of the liver and spleen, and pallor. *Post mortem*, a round duodenal ulcer was found. The second patient was 4 years of age. The abdomen was distended, the spleen and liver were enlarged, the stools contained mucus and blood, but no dysentery bacilli or amoebae could be isolated. *Coli* bacilli were found in large numbers in the stools. On the sixth day after admission a fatal profuse haemorrhage from the bowel took place. *Post mortem*, three round duodenal ulcers were found, as well as a parenchymatous nephritis. Kuttner calls attention to the fact that duodenal ulcer is in reality much more common than is usually supposed. He cites from Moynihan, who has operated on 114 cases during the last seven years; Mayo Robson, who has performed gastro-enterostomy 66 times for this condition; and William J. and Charles H. Mayo, who performed 188 operations for duodenal ulcer. Krug of Kiel found duodenal ulcers in 53 bodies out of 12,020 *post mortem*. Other surgeons and pathologists have brought forward observations in support of the frequency of these ulcers. Collins found duodenal ulcer 42 times in children under 10 years of age. Of these, 17 occurred in infants under 1 year. The condition, however, must be regarded as uncommon in children. With regard to the pathology, Landau ascribed the ulceration to a thrombosis of the umbilical vein and embolus of the vessels of the small intestine, leading to local necrosis. The author considers that in older children the etiology may include plugging of vessels and digestion of the tissue shut off by the plugged vessels. The large majority of the cases show ulcers in the first part of the duodenum, just below the papilla. The association between nephritis and duodenal ulcer is recognized. Kuttner passes on to a brief discussion of those cases in which the duodenal ulcer follows on burns of the skin. He is not inclined to ascribe any etiological rôle to the burns, but regards these cases as coincidences. Of more probable causal nature is the occurrence of pseudo-membranaceous colitis. The action of *Bacillus coli communis* in producing gastric ulcer has been proved experimentally by Fenton Turk. The appearance of the ulcer in his second case, however, led Kuttner to believe that the *Bacillus coli* had not produced it, but that it was a peptic ulcer. He regards his cases and those of other authors as warnings to surgeons to think of duodenal ulcer in infants and young children. Anaemia of unknown origin and occult bleeding from the bowel should be regarded as a possible result of this condition. If the diagnosis can be made, the condition should be treated just like gastric ulcer. When vomiting and haemorrhage is present, rectal feeding should be employed for a time. Infants do quite well on Fühmann's ementa of mother's milk. Alkalies, including carbonate of magnesium, liquor calcei, Carlsbad water, bismuth preparations and styptics may be required. Poultices should not be applied when haemorrhage is present; icebags applied to the epigastrium can be substituted in these cases. He has no experience of operative treatment in young children and infants, but sees no reason why this should not be successfully carried out. Profuse haemorrhage occurring suddenly excludes operation, as death usually takes place within a few hours at most.

2. Radical Neuralgias.

VERGER (*Gaz. Hebdom. des Sci. Méd.*, July 5th, 1908) recommends progressive doses of opium in the treatment of neuralgias referable to the nerve roots. Such neuralgias include most of the sciaticas and nearly all cases of brachial neuralgia. The symptoms in both upper and lower limbs consist of spontaneous pain, day and night, with increased paroxysms, either spontaneous or excited by movements such as coughing; and, objectively, zones of diminished or increased cutaneous sensation, not corresponding to the region of any given nerve, but taking the

form of hands, parallel to the axis of the limb, and varying according to the nerve roots affected. A negative characteristic of these affections is the absence of the painful points of Valleix, so that they can easily be distinguished from other neuralgias of a peripheral origin. From an etiological point of view they may be divided into two groups. In the first group the neuralgia is a sort of precursor of some affection of the meninges of the medulla or cord. Pott's disease, hypertrophic meningitis, vertebral cancer, or meningeal tumours, such as sarcoma; and symptoms, definitely medullary, or pointing to implication of the anterior roots, soon appear. In the second group the neuralgia proceeds from a radical affection, to some extent primitive, such as compression by plaques of syphilitic meningitis, or an inflammation which may be toxic or infectious; and then the neuralgia may present the characters of a specific malady. The diagnosis is difficult at first, the bilateral nature not being always an indication of a grave lesion. But in both groups the prognosis is always doubtful, because, apart from the possibility of very serious ulterior symptoms, radical neuralgia is particularly obstinate, except in cases which yield to antisyphilitic remedies. Local treatment is of no use in essential neuralgia, and surgical interference is apt to fail, division of several nerve-roots having resulted in no improvement in the hands of M. Chavannaz. Verger, in three well-marked cases of radical neuralgia of the limbs, has employed with success the treatment with progressive doses of opium, used by Trousseau for epileptiform neuralgia of the face. In order to obviate the risk of constipation, Verger prescribes a pill containing 2 centigrams of extract of opium with 5 milligrams of belladonna extract. Beginning with five pills a day, he increases the doses by one every second day, until a decided improvement takes place. After about fifteen days of the maximum dose the amount is gradually diminished. Verger's cases comprised an old woman, a young girl, and a man of 44; the first two were cured, and the third, who suffered also from diabetes, was greatly relieved. The maximum doses required were 18, 22, and 24 centigrams respectively. He has never found any serious inconvenience from the treatment, and the relief afforded has been previously sought in vain by means of other remedies. He considers the internal administration of opium preferable to the injection of morphine.

3. Personal Identification.

TAMASSIA (*Gaz. degli Osped.*, August 2nd, 1908) has been working for some years on the dorsal veins of the hands as a means of personal identification. As is well known, these veins differ considerably not only in different people but also in the two hands of a single individual, and it is this marked difference and variability which the author proposes as a means of identification. The veins are rendered prominent either by letting the hand hang down for some time or by applying a ligature, and then the hands are photographed. The surface is a fairly large one, the differences considerable, easily photographed, and require no elaborate measurements or delicate apparatus to register; and even if one right hand may resemble another, it is pretty certain that a right and left hand of any given subject would differ from any other right and left hand. The author describes six chief types:—(1) The arch, used in a general and rather wide sense; (2) the arteriform distribution; (3) the reticulate type; (4) an arrangement like the letter V; (5) like two Y's placed side by side; (6) a mixture of these various groups. The last group is perhaps the commonest arrangement. Whilst the author does not wish to disparage the numerous data furnished by Bertillon's method and by Galton's finger-tip impressions, he believes insufficient attention has been directed to this simple method of identification by means of the dorsal veins of the hands. These veins remain pretty much the same throughout life, and cannot be altered by disease or by intentional fraud, or at least cannot be altered in such a way as to impair their value as marks of personal identity.

4. Prognosis of Diabetic Retinitis.

ROCHOU-DUVIGNEAUD (*Journ. des Prat.*, July 11th, 1908) points out that in certain cases the differential diagnosis of diabetic retinitis and albuminuric retinitis rests much more upon the result of urinary examination than upon the

retinal changes. In both there are vascular and blood lesions, white fibrinous effusions, and haemorrhages. In a case of Bright's disease the appearance of albuminuric retinitis indicates a grave prognosis, and generally speaking its appearance means the entry of the last stages of the disease. If one excepts the short periods of amaurosis of uraemic origin one finds that very few patients suffering from Bright's disease become blind, as they die before the retinitis has seriously affected their vision. In diabetes there may be seen in the retina numerous white spots surrounding or occupying the region of the macula: discrete haemorrhagic points, especially at the periphery: numerous haemorrhagic patches often associated with oedema which partially separates the retina: haemorrhages invading the vitreous and giving origin to cicatricial strings which separate the nerve layer and may cause complete blindness: thrombosis of the central vessels: haemorrhagic glaucomatous lesions causing blindness, and according to the localization and intensity of the lesions, so may the affection of vision be either slight or complete blindness may ensue. Diabetic patients may live for a long time after their sight has been lost, and the prognosis of retinal affections in diabetes is certainly less grave, both as regards the eye and also as regards the duration of life. In some cases the retinal changes have retroceded and good vision has been recovered, whilst in others death has occurred soon after the appearance of retinal changes.

SURGERY.

5. Surgical Treatment of Phosphorus Necrosis.

LEVAI (*Pester Mediz. Chirurg. Presse*, September 6th, 1903) states that among 1,500 persons engaged in Austria in the manufacture of phosphorus matches 250 cases of phosphorus necrosis occur yearly. This disease is not the effect of local irritation, nor does it find its entrance solely through the medium of decayed teeth. It occurs in workmen with perfect teeth, and in one case a regenerated maxilla containing no teeth was attacked. On the other hand, some workers with very defective teeth have worked for many years in a phosphorus manufactory without developing necrosis. Phosphorus attacks the organism as a whole, and affects other bones besides the jaw. A phosphorus worker of 40 broke two ribs after an insignificant blow and twice fractured his forearm. A forty-year-old packer broke her femur four times in three years. (None of these patients had syphilis.) In 11 cases Levai examined histologically the removed bone, and in two cases portions of bone chiselled out of the sound maxillae, and found that the endothelium of the blood vessels of the bone is diseased in those who have worked for a long time with phosphorus. This makes the bones brittle, and as thrombus formation readily occurs in diseased vessels, predisposes to necrosis. To cause such a predisposition four or five years' systematic employment in a phosphorus-containing atmosphere is sufficient, and, once it exists, a worker cannot avoid his fate, even by giving up his injurious occupation. Levai urges the importance of early operation. Waiting for the formation of an involucrum is accompanied by a mortality of at least 21 to 22 per cent. The early operation is fraught with hardly any danger, and, even if the operation is not sufficiently radical, the mere removal of dead bone makes the patient's condition more tolerable. Death usually occurs with obstruction of a whole branch of a vessel at once throughout the whole thickness of the bone, so that the necrosis quickly spreads. Even if an involucrum forms, it is imperfect and dies subsequently. After an early operation the periosteum left behind is adapted to new bone formation, and good functional and cosmetic results are attained where the whole maxilla is removed, especially when, directly after the operation, a provisional substitute for the jaw is inserted. Substitutes made of tin are best: strong wire may be used. Caoutchouc is bad for aseptic reasons. Levai always carries out the operation from the oral cavity, partly from a cosmetic point of view, partly because when the mouth is opened from without the wound renders nourishment exceptionally difficult. In these weakened patients good nourishment is of the greatest importance. In slight degrees of necrosis Levai operates under a local anaesthetic: with far-reaching necrosis, under the morphine-ether narcosis. After removing the loose teeth, he makes an incision along the edge of the sockets reaching to the bone—around the dead bone this is easy—and resects in healthy bone. When the larger half of the maxilla is dead he removes the whole bone at once, as his experience shows that when half of a

jaw-bone is dead the other part dies shortly after. When the incision is carried at once down to the bone and the periosteum pushed back from the entire bone haemorrhage is usually insignificant. In the after-treatment frequent irrigation of the mouth is necessary: he uses a 2 per cent. boric acid solution. Levai gives notes of 7 cases of very successful operations exhibited before the Buda-Pesth Medical Society in 1907.

6. The Treatment of Burns.

RENNER (*Zentralbl. f. Chir.*, No. 30, 1903) reports that in the treatment of burns of all degrees he has obtained much success from the use of a powder made up by one part of subnitrate of bismuth to two parts of kaolin. The burnt surface, after it has been thoroughly cleansed, is covered by a thick layer of this powder, over which is bandaged a layer of sterilized gauze, the whole being finally covered by thick layers of wadding. This dressing is changed every day so long as there is much discharge, the injured area being submerged in a partial or a complete bath, according to the extent and the situation of the burn. This powder, the author states, is a very active absorbent, and speedily takes up fluid from the burnt tissues, which are converted into a black and desiccated eschar. In burns of a mild degree the area, after the use of the powder, is covered by a thick crust, which serves as an excellent protection during the growth of the new epidermis. By this treatment, for which are claimed the advantages of simplicity and cheapness, together with the capacity of arresting free secretion and preventing septic infection, pain, it is asserted, is relieved and the temperature kept down. In some few cases there has been an urticarial rash with much itching around the burn, but this, the author states, soon disappears after a temporary suspension of the use of the powder.

7. The Surgery of Pancreatic Contusions and Fistula.

PIQUÉ (*Rev. de Gynéc. et de Chir. Abdom.*, July-August, 1903) reported a case of partial removal of the pancreas. A boy, aged 13, was knocked down, and a cart wheel passed over his abdomen. Signs of localized peritonitis developed above the umbilical level, but not until the third day. Piqué opened the abdomen and discovered a retrogastric haematoma, in the midst of which lay the pancreas, with its tail completely detached and beginning to slough. He removed it and packed the cavity which had contained the effused blood with gauze. The boy recovered, but a pancreatic fistula developed: it closed spontaneously, however, in a few weeks. Injuries confined to the pancreas are not frequent. Piqué has collected 20 cases; 14 underwent operation (suture or tampon), 10 recovered. Fistula nearly always follows these procedures; it heals up spontaneously and heals quickly, provided that the patient is submitted to an antidiabetic treatment. Schwartz, in discussion, related another case of contusion of the pancreas treated by the tampon; a fistula developed as usual, but closed spontaneously. Regnier stated that he successfully treated a case of pancreatic fistula following contusion of the abdomen by antidiabetic diet. Tauber cured, by enforcing that diet, an obstinate case of pancreatic fistula following an operation on the stomach. Two other pancreatic fistulae following complicated surgical procedures on the stomach healed spontaneously.

OBSTETRICS.

8. Criminal Abortion.

H. MARX (*Berl. Klin.*, May 18th, 1903) propounds a question of ethics: Should a medical man who is called in to attend a case of criminal abortion notify the police of the nature of the case? The medical man is never compelled to do so in Germany, and in most cases he would not be justified in violating professional secrecy. Dr. Marx, however, believes that there are cases in which the medical practitioner would have solid excuse for so doing. He quotes the following illustration: The patient died, but before death told the doctor the name and address of the washerwoman who had procured abortion for her. The doctor considered it to be his duty to denounce the woman, in the interest of the public. The majority of abortionists are women, and have a regular plan of campaign in their business. First they try the so-called abortifacients, which are very rarely successful. Next baths, massage, and douches are employed. Marx finds that the only certain drugs for the induction of labour or abortion are phosphorus and mercuric chloride, and both of these usually kill the

mother as well as the child. As the mild expedients rarely lead to the termination of the pregnancy, the patient is then subjected to instrumental interference, which takes the form either of the passage of a catheter or sound or the injection of a fluid. In Berlin the latter is more common, and frequently takes the shape of a soapy solution. The medical man is at times asked in a court of law whether this or that internal remedy is capable of terminating a pregnancy. While it cannot be denied that at times one or the other may succeed, there is no doubt that nearly all the drugs used by these women are inert. Very hot vaginal douches may succeed, but the temperature of the water for this purpose must be at least 104° F., and the fluid must be directed immediately towards the os uteri. When an abortion has taken place the medical man may be asked whether a manipulation which can be proved to have been resorted to can be made responsible for the effect. The time elapsing between the manipulation and the abortion is important. From twelve to twenty-four hours is the usual interval between the interference and termination of the pregnancy. A not uncommon trick of abortionists is to advise the patient to fall after the uterine injection has been carried out. In discussing a case in which the prisoner was charged with procuring criminal abortion with an instrument, and in which the defence raised was that the patient "overreached" herself in taking a book out of a bookshelf, Marx points out that the argument which he used in court was that no one could believe that if a spark were thrown into a barrel of gunpowder, and then a sharp knock was given to the barrel, the explosion could be due to the knock. When death follows abortion in response to acute sepsis, one is justified in assuming that the abortion was criminally procured. Quacks rarely realize the normal anteflexion of the uterus and wounds perforating the vagina or cervical canal are not infrequent. Sudden death may take place in connexion with induced abortion. He cites the case of a "masseuse" who succeeded in separating a six months ovum from the uterine attachments and caused a small superficial wound in the mucous membrane. The ovum was intact. Death took place from an air embolus. Death from scalding also may follow the manipulations of these abortionists. The diagnosis of pregnancy and abortion after death is easy, if the case is recent and the insertion of the placenta is still visible. In late cases, it may, however, be extremely difficult. The presence of decidual cells and of a corpus luteum in the ovary may assist the diagnosis. During life the diagnosis of a pregnancy which has been interrupted by abortion is made forensically as the diagnosis of pregnancy is ordinarily made in practice. It must be remembered that an abortion can take place without the destruction of the hymen. In conclusion, he finds that in towns the induction of abortion is relatively common, while in the country districts child murder is relatively frequent, and therefore abortion is proportionately rare.

GYNAECOLOGY.

9. Vaginismus and Appendicitis.

RICHELOT (*Bull. et Mém. de la Soc. de Chir. de Paris*, November 3rd, 1908) discussed at length the etiology of vaginismus at the October meeting of the Société de Chirurgie de Paris. He pointed out that the local irritation theory was faulty. In many cases the mucosa and integuments are found to be quite sound, free from fissures and ulcers, and not subject to the irritation of any vaginal or uterine discharges; on the other hand, women with eczema and other causes of irritation in the vulvo-vaginal region often tolerate coitus without ever suffering from true vaginismus, even when connexion is actually painful. The neurosis theory is probably correct. Richelot reports a case in which the patient was a woman aged 28, married for five years. She had been troubled for fifteen years with a complication of objective and subjective symptoms. At first mucous enteritis set in, and was followed by obstinate constipation, chlorosis, mental depression, and loss of will power. At last, when Richelot examined her, he found all the evidences of chronic inflammation of the appendix. The patient had never been able to submit to complete coitus. The vagina and vulva showed no morbid appearances, but introduction of the finger caused great pain. Richelot removed the vermiform appendix, which he found buried in adhesions connecting it with the caecum, and filled with small stercoral calculi. He did not operate on the vulva. After convalescence the patient's health steadily improved, and at the end of two

years the bowels were regular without drugs, and all neuroses had disappeared. But the vaginismus ceased when the operation was performed, for when the patient returned to her home coitus was from the first quite practicable without the least pain. In discussing the case, Lucas-Championnière agreed with Richelot's opinion on the two theories. Local irritation did not necessarily cause vaginismus, and was not invariable in cases where that affection was present. Distant sources of irritation, on the other hand, were often to be defined. After ovariectomy and hysterectomy vaginismus was not rare. Lucas-Championnière in 1879 performed Porro's operation on a dwarf—one of the earliest instances where mother and child were saved. The artificial menopause did not cause much general disturbance, though there were periodical hæmorrhages from the lungs and rectum, and the patient was able to work for her living; but coitus, which she sought eagerly as there was no more chance of the perils of maternity, became impossible on account of the most severe vaginismus. Lucas-Championnière examined the vulva and could find no erosions.

THERAPEUTICS.

10. Treatment of Pancreatitis.

DR. DREESMAN (*Med. Klinik*, October 4th, 1908) considers operation the only effectual method of completely eliminating the pancreatic secretion, which is being abnormally distributed to the body, as soon as possible. Acute pancreatitis, untreated, is undoubtedly, with rare exceptions, fatal. Death is the direct or indirect result of the action of the pancreatic ferment upon the tissues, acting either directly upon these or being carried thereto by the blood or lymph vessels. In exceptional cases cure by means of conservative, purely symptomatic treatment (washing out the stomach, irrigation of rectum, administration of oleum ricini) is not possible: the hopes raised of immunization by means of trypsin and by serumtherapy have not yet been realized. Dreesman recommends opening the omental cavity through the gastro-colic ligament. The cut should be between the ensiform process and the navel, or a little more to the left, according to the site of the greatest sensitiveness to pressure or resistance. A blood-stained peritoneal exudate, if incarceration or mesenteric thrombosis can be excluded, signifies in all probability pancreatitis and justifies opening the omental sac. The inflamed gland and peritoneum should only be incised when the pancreas is much swollen, and its peritoneal covering uninjured, otherwise severe hæmorrhage, only controlled with difficulty, may result. A suspected focus of suppuration may always be punctured. Dreesman recommends drainage by gauze plugs down to the surface of the gland, which can be changed several times a day, and if the secretion is very great (for example, ½ litre or more) a drainage tube in addition. Washing out the abdominal cavity is not recommended unless the patient's condition, especially the pulse, is good, which is not generally the case; the mesentery is, in these cases, moreover, very easily torn. Drainage of the bile duct may be useful, even in the absence of gall stones, when the gall bladder contains abnormal bile resembling tea. As Robson recommends, calcium chloride is useful in lessening hæmorrhage, and may be given in doses of 2 to 4 grams thrice daily for one to two days before the operation, and 4 grams thrice daily by rectal injections, after the operation, for two days. If in eight to fourteen days a fistula has formed, a tube usually suffices for drainage. Action on the skin may be prevented by antiseptics (airol, viroform), and in one case Burnmeister used a special aspirating pump with success. The diet should be regulated. Secretion from the pancreatic fistula is very profuse after carbohydrates, is less after albuminous foods, ceases after fatty diet, is excited by hydrochloric acid, and is hindered by sodium bicarbonate. Of 118 cases, taken from the literature, in which an operation was undertaken, including Dreesman's 5 own cases, 40, it appears, were treated with tamponade of the pancreas: of these only 8 died (20 per cent.). Recovery took place in 53 of the 118 cases, mortality being 55 per cent. In chronic pancreatitis special diet and administration of pancreas preparation are useful. Schmieder recommends iodide of potassium; Robson, in cases of obstinate constipation, calomel, followed by saline purges, and later by bismuth subnitrate and small doses of opium. In many cases operation becomes necessary, on account of great emaciation or pain, and its nature will depend on the cause of the pancreatitis. When dependent upon cholelithiasis, its most frequent cause, cholecystotomy or cholecystenterostomy should be undertaken.

11. Treatment of Neurasthenia.

A. D. ROCKWELL (New York *Med. Record*, December 5th, 1908) discusses the treatment of true neurasthenia—not the condition of autointoxication often called by that name, and resulting from too much eating and insufficient exercise. The symptoms of the disorder are, he says, astonishingly numerous, while the patient may appear in good general condition. It is important to distinguish between hereditary and acquired neurasthenia. In hereditary cases slight irritations will produce severe symptoms. Neurotic and hereditary instability is an important factor in prognosis and etiology. A typical neurasthenic is easily affected by alcohol. One important causative factor in men is sexual excess out of wedlock. Neurasthenia is rare in persons suffering from grave organic diseases. In many cases rest is not as good treatment as occupation. When there is cerebral excitement with physical exhaustion rest is imperative. For lithaemics who suffer from autointoxication work is a good remedy. The use of few drugs is indicated. When any are given, the bromides are useful to calm irritation. Electricity is the best remedy for the neurasthenic. Light and heat are also valuable. An intelligent encouragement and control of the patient are essential. Sympathetic consideration must be shown for his symptoms.

12. Isopral in Cardiac Affections.

PETERS (*Deut. med. Woch.*, October 29th, 1908) discusses the value and advisability of administering isopral to patients suffering from various forms of cardiac disease. In referring to the literature on the subject, he finds that certain clinicians have expressed the opinion that isopral is endowed with a toxic effect on the heart. This he denies. Actual reports of cases in which isopral is supposed to have produced undesirable actions on the circulatory system are few, and most of these, he thinks, can be explained without difficulty. The symptoms complained of were in all cases symptoms which could readily arise in the course of the disease which was being treated, and he therefore objects to assigning the cause to the drug which was given. He has given isopral in a number of cardiac patients, and has not met with any toxic effects either on the cardiac nerves, or on the vascular system, or on the blood pressure. The heart itself is not attacked by this drug, nor have any deleterious effects been noticed in any of his heart patients during the exhibition of the drug. In cases in which salicylate of sodium was not well tolerated he obtained a good pain-relieving action from isopral. He therefore recommends isopral as a safe hypnotic, which can be given even in advanced heart disease.

PATHOLOGY.

13. Rhythms of Growth Energy in Mouse Cancer.

G. N. CALKINS (*Journ. of Exper. Med.*, May, 1908) holds that three factors must be taken into account in considering the continued propagation of cells in experimental mouse cancer. In addition to (1) the inherent capacity for division of the cancer cells, and (2) the natural resistance of the inoculated animals, there is a third factor which he describes as "the potential of infectivity of the cancer cells." This third condition is characterized by more or less regular rhythms, rhythms distinguishable from the rhythms of growth energy of the cancer cells which in all probability occur within the individual mouse. Cancer cells differ from epithelial cells by virtue of this potential of infectivity combined with that of division energy, the latter quality being attributable to the action of stimuli and not to the liberation of a restrained growth power of embryonic tissue. Infectivity distinguishes all cancerous growths from normal epithelium and from benign tumours or teratomata. "The rhythms of infectivity of cancer cells . . . appearing as they do in successive batches of mice which we may legitimately assume to have like powers of resistance, must have their cause in the cancer cells themselves. These cells, therefore, must be equivalent to parasites, or else parasites are contained within or associated with them." It is suggested that there may be some organism which, acting like *Plasmodiophora brassicae* within vegetable cells, underlies the infectivity of cancer cells, and provides the stimulus for their continued proliferation. This is the assumption which will best explain

the numerous cases of cage infection. This mysterious organism, like the organism of yellow fever, may reside within the cell protoplasm but be too small to be recognizable by the microscope. Calkins also suggests that the spirochaetes often found in mouse cancer may have something to do with the disease. They may prepare the soil for cancerous growth, or they may have intracellular stages in their life-history which are too minute to be seen.

14. Prevention of Tropical Abscess of the Liver.

LEONARD ROGERS (*Archives of Internal Medicine*, June, 1908), from a seven years' exceptional experience of this disease in Calcutta, has arrived at the conclusion that tropical abscess of the liver can be prevented by the early diagnosis and treatment of the presuppurative stage of amoebic hepatitis. In a series of papers published in the *BRITISH MEDICAL JOURNAL* between 1902 and 1906, the author has traced the relationship between tropical abscess of the liver and amoebic dysentery, and the good effects of the treatment of acute hepatitis by large doses of ipecacuanha, and of abscess by aspiration and injection of bi-hydrochloride of quinine. Although large doses of ipecacuanha are commonly given in cases of amoebic dysentery complicated by hepatitis, the author advises this treatment for hepatitis when not accompanied by dysentery, and the considerations which led him regularly to adopt it are the finding of dysentery associated with 90 per cent. of tropical abscesses of the liver, and the fact that in many patients dying from liver abscess, without history or symptoms of dysentery, amoebic ulcers are found *post mortem* in the upper part of the large bowel. He therefore regarded hepatitis accompanied by leucocytosis as an indication of the presence of latent amoebic ulceration of the large bowel, which indicated large doses of ipecacuanha for its cure. The results of this treatment have been so successful that during the last two years no instance has occurred of abscess developing while the patient was in the European General Hospital, Calcutta. The drug is given in 30 grain doses, twenty minutes after a dose of tincture of opium, no food or drink being given for several hours before and after the dose. This is in order to avoid vomiting. It should be given daily at first, and continued at increasing intervals for at least two weeks. There is as a rule ample time for the diagnosis by blood examinations to be made, and the ipecacuanha administered before the formation of an abscess, as the presuppurative stage is never less than two weeks, and extends to a month in about 50 per cent. of cases.

15. Haemolytic Reaction of Blood Serum in Malignant Disease.

W. FISCHER (*Berl. klin. Woch.*, May 4th, 1908) states that Kelling read a paper at the German Surgical Congress in 1906 on a new haemolytic reaction of blood serum of persons suffering from malignant tumours, and drew diagnostic and statistical conclusions from his observations. Kelling believes that the cell acts as a parasite in cancer, and that a specific haemolytic power is present in the serum for blood corpuscles of animals of other species. Other workers have studied this problem. Von Düngring subjected the arguments to a severe criticism, and concluded that Kelling's reaction was worthless. Rosenbaum found that Kelling's reaction proved positive in 54 per cent. of cancer cases affecting the gastro-intestinal tract, and from this he considered that the matter should be studied more closely. The American observers have found that a haemolytic action is present. Weil found that the serum of dogs with tumours almost always revealed a powerful haemolytic action toward the blood corpuscles of healthy animals of all species; that the blood corpuscles of these dogs resisted solution by serum more than the blood cells of normal dogs; and that the serum of dogs which had no tumours rarely possessed any haemolytic action. The author set himself the task of examining the position of Kelling's claims, and summarizes the results which he obtained as follows: The blood serum of many patients suffering from malignant tumours possesses a marked haemolytic power toward the blood cells of various animals. The haemolytic reaction is, however, not specific for the blood cells of a particular species as Kelling assumed. The haemolytic reaction is not specific for malignant tumours. It occurs in other diseases, notably in pernicious anaemia and tuberculosis. He details the scope and type of his experiments and shows that his conclusions are justifiable as a result of his observations.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

16. Vasomotor-trophic Neuroses.

In dealing with the prognosis and treatment of vasomotor-trophic neuroses, Cassirer includes acroparaesthesias, Raynaud's disease, erythromelalgia, sclerodermia, sclerodactylia, and Quincke's fugitive oedema (*Deut. med. Woch.*, October 29th, 1908); he, however, recognizes many transition forms and cases in which it is impossible to define the disease by any one name. At times these vasomotor-trophic neuroses appear as accompaniments of other nervous complexes. The facts that in these neuroses a common localization is met with and that the sensory and secretory disturbances are more prominent than the motor disturbances speak for a common factor of the etiology. He regards all the diseases grouped in this way as manifestations of disturbances of the sympathetic system. They are, further, all functional nervous disturbances. For this reason the application of the word "neurosis" is justified. All the forms tend to manifest themselves in periodic attacks. The prognosis, taken generally, is good as far as life is concerned, and also as far as the transition to organic nervous disease. The course is, however, generally an obstinate one. General lines for treatment can be set up on the basis of the common factors of these conditions. Everything should be done to oppose the development of the inherited or acquired neuropathic diathesis. The individual measures are best dealt with separately for each disease. Acroparaesthesias are characterized by unpleasant, irritating, and even painful sensations in the fingers, hands, and forearms, accompanied by the phenomenon of "dead fingers." At times cure occurs; but, inasmuch as this form usually accompanies general nervousness and not infrequently arises as a climacteric phenomenon, the majority of the patients do not get better. The treatment consists in avoiding all conditions which might lead to nervous symptoms, and especially avoiding the touch of cold, wet objects, cold water, etc., as well as all forms of over-exertion. Faradic hand baths do good, as do galvanic baths, and Swedish gymnastics at times yield good results. Raynaud's disease is characterized by the appearance of symmetrical superficial dry gangrene, chiefly affecting the nose, fingers, ears, chin, and toes. Ulceration near the nails and what are known as local syncope, local asphyxia, and local rubor are seen. Great pain often accompanies this form. The prognosis is doubtful, although the disease can scarcely be said to threaten life. In the treatment the alleviating of pain is usually the first duty of the physician. Pyramidon, opium or morphine are the best drugs for this symptom. Electricity offers a useful action of the process. Dry heat and massage as well as passive movements are useful in many cases. The gangrenous parts should not be removed surgically too early, and even if no operative treatment is undertaken, the resulting scars are often much smaller than would be expected. Local hyperaemia has yielded quite good results in recent times. Tonics and good food are necessary. Amyl nitrite and adrenaline have proved disappointing. Erythromelalgia is characterized by redness and pain in a limb or portion of a limb. It is a rare condition. As a rule the affection, unlike Raynaud's disease, is not symmetrical. The treatment is purely symptomatic and consists in raising the limb and applying cold. Sclerodermia and sclerodactylia may be treated in a similar manner to Raynaud's disease. Fugitive oedema is a much more important and complicated condition than is usually supposed. The swelling attacks the mucous membranes, the muscles, the joints, the tendon sheaths, and probably the serous membranes, the meninges, etc., as well as the skin. The symptoms are therefore different according to the site of the oedema. When the larynx is attacked, the case may end fatally, but, as a rule, life is not endangered. The prognosis is bad or doubtful as far as complete recovery is concerned. The treatment consists in regulating the diet and motions of the bowels. Quinine is much recommended, atropine at times appears to do good, and arsenic also may be of value when the other drugs fail. The itching requires special treatment and the tendency to vomiting may even call for morphine.

17.

Lobar Pneumonia.

NORRIS (*Amer. Journ. of Med. Sciences*, November, 1908) deduces some valuable observations from a study of the

statistics of 445 cases of lobar pneumonia admitted to the Philadelphia General Hospital during a period of nearly three years, starting from the time of the inauguration of the fresh-air treatment, with a resulting decrease in mortality. The male patients were isolated in a special ward in which the windows were constantly kept wide open regardless of weather or temperature, whilst the females had, from lack of room, to be treated in the general wards with only the ordinary ventilation, but the statistics of the two sexes have been kept separate. Compared with statistics compiled some years previously and prior to the adoption of the fresh-air treatment the mortality showed a decrease of 10 per cent. for the males, while the mortality in the case of the females was nearly double that of the males. Besides the constantly-open windows and doors therapeutics was largely symptomatic in character, delirium and insomnia being treated with bromides, opium, etc., and asthenic cases with strychnine, caffeine, ammonia, digitalis, etc. The use of alcohol is deprecated, since the drug does more to relax the vasomotors than to stimulate the heart, and its use appears to be gradually falling into disfavor. Cold-water sponging was frequently used, and found to be most beneficial, not so much in reducing temperature as in toning up the vasomotor system. Digitalis was largely used, though in febrile cases it is of practically no value. Of complications, acute pericarditis occurred in 8 cases, all of them fatal, and this incidence of pericarditis corresponds very closely with the experience gathered from a study of the general literature. Acute endocarditis occurred 3 times, and all the cases terminated fatally. There were 2 cases of empyema, giving 1 recovery and 1 death. Pulmonary abscess occurred in 2 instances, with 1 death. There were 3 cases of meningitis, with 2 deaths; and acute arthritis occurred 3 times, with 2 fatal cases. Otitis media was noted in 6 cases, of which 1 died, and parotitis was recorded once, with recovery. Acute peritonitis was only met with once, ending in death, and acute colitis occurred in 4 fatal cases. Albumen was present in 78 per cent. of the cases, and a clinical diagnosis of acute nephritis was recorded in 16 of the cases, 14 of which ended fatally. With regard to the fresh-air treatment, the author considers that anyone who has the courage to try it will never abandon it, since his experience shows that its use gives a greater sense of well-being to the patient as well as a decreased mortality, and this without any deleterious effects.

SURGERY.

18. The Surgical Aspects of Ionic Medication.

TUFFIER (*Bull. et Mém. de la Soc. de Paris*, No. 33, 1908) gives the results of a careful study he has made, from both experimental and clinical points of view, of the method of electrical ionic-therapy or ionic medication, in regard to its probable value in surgical practice. The method, the principles, indications, and technical details of which have been fully described by Dr. Lewis Jones (*Proc. Roy. Soc. Med.*, vol. i, No. 5), aims at the removal of subcutaneous lesions by driving medicinal chemical substances through the healthy skin into the deeper tissues by electrical means. The substances which can be used in this treatment act on the deep tissues differently and much more efficiently, it is held, when introduced by electrolysis than when they are applied by the simpler process of hypodermic injection. The diseases in which ionic medication has hitherto been found useful are rodent ulcer, local septic conditions, warts, and lupus; it has also been tried with promising results in cases of chronic arthritis and of neuralgia. Although many powerful agents—such, for instance, as iodine, chlorine, chloral, phenol, and alcohol—are not available for this treatment on account either of loss of their properties when in the ionic form, or of insolubility or incapacity of dissociation when dissolved, there are, Dr. Lewis Jones has pointed out, a very large number of active substances which can be used. The agents most likely to be found of service are not only inorganic salts, but also such useful organic compounds as quinine, cocaine, strychnine, adrenalin, and salicylates. Tuffier, who describes in the first place some experiments with a stained solution of nitrate of silver, states that there can be no doubt that

chemical substances may by the aid of the continuous current be introduced beyond the healthy skin, and there be absorbed more or less rapidly. It is not quite clear in the author's report how far such solutions may be driven, but much stress is laid on his conclusion that their penetration is superficial. It is certain, he states, that the medicinal agents cannot pass beyond the cutaneous covering, and whatever the modifications effected in the concentration of the employed solution, and in the electrical intensity, he has never succeeded in reaching the subcutaneous cellular tissue. The author confirms the previous observations that the action of chemical substances on the subcutaneous tissues is influenced by their mode of introduction. Trypanoth, when injected in a 1 per cent. solution by the usual method of injection, forms an unstable combination with the cellular protoplasm, and is speedily dissolved and removed. On the other hand, when introduced by the action of the electric current, the particles of colouring matter are closely combined with the cells of the dermis, and are rendered less soluble. These experimental results serve to explain the observations of some authors that substances introduced by electrolysis pass much less slowly into the urine than those introduced by way of the stomach or by subcutaneous injection. Tuffier has obtained good results from the ionic treatment in painful affections of the surface of the body, as, for instance, facial neuralgia. He failed in two cases of epithelioma of the face, and is disposed to think that penetration is more difficult through cancerous than through healthy tissues. His experience of salicylic ions in the treatment of chronic joint affections has not been very favourable. In some cases relief certainly followed the introduction of these ions, but it was found that equally good results could be gained in similar cases by using as electrodes simple water or chloride of sodium. In two cases in which the ionic method was practised with good results for supposed ankylosis, the articular weakness and rigidity were found to be really due to pain localized to the surface of the joint. Under the influence of the electric current the pain in both cases ceased, and the adjacent joint, which was quite healthy, very rapidly regained its normal motility. In reviewing the results of his experimental and clinical work on this subject, the author concludes that the benefits of ionization should not be exaggerated, and that it is necessary in regard to this method to consider two very distinct actions. In the first place there is the assured medicinal action which is absolutely restricted to the skin, but which, thanks to the more or less soluble combinations formed in the cellular protoplasm, may have such special effects that, even if electricity does not carry the therapeutic agent to the diseased part, it does not follow that the electrolytic introduction is incapable of aiding in certain cases the good effects of the current. The second action, which is due to the biological phenomena produced under the influence of the current, is independent of the solution employed, owing to the osmotic action excited by the displacement of the ions of the organism.

OBSTETRICS.

19. Gangrene of Leg from Thrombosis in Pregnancy.

JARDINE (*Journ. Obstet. and Gynaec.*, of the British Empire, March, 1938) reports a case of a woman who had excellent health during her pregnancy until within a fortnight of term, when she began to suffer from cramp in her right leg and foot, alternating with sensations of tingling and numbness. Six days later the pain was so great as to necessitate injections of morphine, and the foot and leg were white and cold, no pulsation being felt in the tibial arteries. The heart sounds were slightly roughened in the aortic area, but otherwise pure. Labour commenced eight days after the onset of these symptoms; the child, which was delivered with forceps, was hydrocephalic, and did not survive. The puerperium was practically uneventful, but the gangrene of the leg progressed steadily, and ten days later she was transferred to the care of the surgeon, who amputated just below the trochanter. All the vessels in the face of the stump were thrombosed, and only the femoral artery and vein were tied. No tourniquet was used, but the abdominal aorta was compressed during the operation. Subsequently the patient experienced severe pain in the left foot and leg, and the pulsation of the tibial arteries, and later of the femoral in Scarpa's triangle, could not be felt. The flap also became gangrenous, and the covering of the stump was destroyed.

The patient refused to have any further operation to remedy this. The circulation in the left limb had recovered and the foot was warm when the patient left the hospital. The cause of the thrombosis is not clear; the cardiac lesion was of the slightest, the process of blocking seems to have been a gradual one of some weeks' duration, although the pain only became marked a few days before admission to the hospital. It is unlikely that the hydrocephalic condition of the child should have had any bearing on the condition.

GYNAECOLOGY.

20. Cancer of Stomach Secondary to Cancer of Fallopian Tube.

EVERKE (*Monatsschr. f. Geb. u. Gyn.*, October, 1938) removed a right Fallopian tube subject to primary cancer, in February, 1932. The patient was 46; she had suffered from purulent vaginal discharge shortly after marriage, but had borne two children after wards, her last confinement being twelve years before the operation. She consulted Everke for bloody discharge, and he detected a tumour of the size of a fist, apparently in the parametrium. It proved to be an adeno-carcinoma of the right tube which had invaded the parametrium and adhered to the rectum and sigmoid flexure. The tube, healthy at its uterine end, was removed, the uterus sutured to the parietes, and a wound in the rectum made during the separation of the tumour closed by suture. In September, 1933, dyspeptic symptoms set in and a tumour the size of a goose's egg was detected in the epigastrium. It was a cancerous growth in the stomach, and proved fatal by March, 1935—a month over three years after the operation.

THERAPEUTICS.

Heart Stimulants.

21. HORATIO C. WOOD, Jun. (*Amer. Journ. of Med. Sci.*, November, 1938), continues his remarks to the digitalis group of drugs. There are three factors in the action of these which are of clinical interest. These are (1) the cardio-inhibitory action, prolonging the diastole and slowing the pulse; (2) the tonic action on the heart muscle, making the systole more powerful and complete; and (3) the vaso-constrictor action. The slowing of the pulse-rate is the most important part of the action of digitalis, because this is brought about by the prolongation of the diastole. With a prolonged diastole the ventricle becomes more completely filled, and so, from the very beginning of the systole, the cardiac contraction is occupied in sending blood out into the vessels, and no part of its power is wasted in contracting down on to the contained blood, as when it is partially empty to begin with. Economy in the work of the heart is in this way effected, a point of much importance in cases of chronic heart disease where it is essential to make the burden of the feeble heart as light as possible. The importance of the tonic action on the heart muscle lies in the fact of its preventing this muscular relaxation during the prolonged diastole from going on to permanent dilatation. These effects are produced mainly on the left ventricle; so that in some cases of mitral regurgitation with much hypertrophy of the left ventricle it may happen that the action of this chamber is so disproportionately strengthened that the left auricle and right ventricle are relatively weakened, and may dilate before the powerful regurgitant stream from the left ventricle. The vaso-constrictor action is less harmful than is often supposed. It keeps up the pressure in the aorta, on which depends the filling of the coronary arteries, and consequently the nutrition of the heart. It is harmful when, from degeneration or other causes, the cardiac muscle is too scanty to respond to the tonic action of the drug. With regard to the various members of the group, squills and apocynum are of restricted usefulness from their irritant action on the kidneys and stomach; strophanthus has less tendency than digitalis to produce a cumulative toxic effect, though its action on the vessels is, in spite of what is widely believed, the same as that of digitalis; adonidin appears to act on the heart in a similar way to digitalis, but relaxes the coronary arteries. The author considers digitalin, digitalein, and digitoxin, the so-called active principles of digitalis, unsatisfactory. Experimentally, they are none of them found to produce the characteristic therapeutic effects of the drug, while digitoxin possesses the cumulative toxic properties to a marked degree.

PATHOLOGY.

32. On Infection Path of the Tubercle Bacillus.

REICHENBACH (*Zeit. f. Hyg.*, Bd. 60, H. 3) studied the relative probability of alimentary and inhalation infection. It has been shown that both alimentary and inhalation infection are possible, but nothing has been done to show the relative probability of the two modes of infection. A suspension of known strength was prepared; part of it was used for feeding experiments and the other part for spray infection. The quantity used in spraying and feeding was then estimated in relation to the minimal fatal dose. For feeding experiments 140 millions were necessary, whilst spraying only required 40,000. This was the number used in producing the spray. Corrections based on the data of other observers were then made for the number of bacilli which were not inhaled at all and for the inhaled bacilli which never reached the lungs. Only one-thirty-fifth could have been inhaled, and of these only one-third ever reached the lungs. Applying these corrections we find that 357,000 times the inhalation dose is required to produce an alimentary infection. These results were obtained with the guinea-pig. With goats, being unable to obtain sufficient animals, he never reached the non-lethal inhalation dose, but he was able to show that the inhalation dose was at the most only one-hundredth the alimentary dose. Using smaller doses, repeated fifty times, he found that the minimum for the guinea-pig was 800,000 for the alimentary dose. To exclude lymphatic absorption from the nose he did some controls with the nostrils plugged. The results were identical.

33. Etiology of Tuberculosis.

ALEXANDER (*Zeit. f. Hyg.*, Bd. 60, H. 3) experimented with the rabbit to investigate (1) the susceptibility to the different modes of infection, and to (2) the two types of bacilli. The human bacilli were obtained from sputum by filtration, then enumerated and control experiments were performed with guinea-pigs to show that inhalation of 80 bacilli uniformly caused a fatal tuberculosis. The results on the rabbit were: (1) *Minimal active dose*—(a) For inhalation: Human bacilli, 50,000; bovine, 100. (b) For feeding: Human type, quite inactive; bovine, 50 mg., in five doses of 10 mg. (c) For intravenous injection: Human type, 50,000; bovine, 50 bacilli. (2) *Maximal inactive dose*—For inhalation: 25,000 and 50,000 respectively; for feeding: 180 mg. and 50 mg. respectively; intravenously: 8,000,000 and 5,000 respectively. The qualitative results are also interesting. Subcutaneous infection with human virus is rarely fatal, whilst with bovine virus it is uniformly fatal in two to three months. Intravenous injection with human virus (1 mg.) is rarely fatal, but when the animal is killed in three months there is found a slight pulmonary lesion without any glandular infection. An intravenous injection of $\frac{1}{10}$ mg. bovine virus causes a general tuberculosis, fatal within five weeks. He concludes that in rabbits inhalation is more fatal than feeding, and that this applies to both strains of bacilli. The bovine type is much more fatal to the rabbit than the human type. REICHENBACH and BOCK (*Zeit. f. Hyg.*, Bd. 60, H. 3) discuss the permeability of the intestine towards the tubercle bacillus. Previous experimenters have obtained positive results, but Reichenbach and Bock claim that these results are invalidated for practical purposes by some unnatural conditions. The bacilli have been given in huge doses, or the stomach tube has been used, or the blood vessels have been opened up in making an artificial gastrostomy, or the intestines have been injured by large doses of purgatives, or the animals had been starved for a long time. They avoided all these sources of error, and used quantities of bacilli which were accurately estimated. Oettinger has shown that when bacilli are introduced into the venous circulation they are not, as some have assumed, retained in the lungs as a filter, but that most of them are found in the liver. Hence, when bacilli are found in the lungs and not in the other organs, the presumption is that they have been inhaled and not that they have arrived there from the blood. Sublethal doses of bacilli were used in most experiments. The dogs took the bacilli suspended in omeza, the guinea-pigs in turnip mash. They were killed by stunning, and in removing the lungs every care was taken to avoid opening the oesophagus, as this was found to invariably result in contaminating the lungs. In 1 dog, out of 4, bacilli were found in all the organs. Out of 27 guinea-pigs, bacilli were found in the organs of 2 only, and this occurred when a dose above the fatal alimentary dose had been given. They conclude that the alimentary canal is not permeable to the tubercle bacillus, and that this fact is the only satis-

factory explanation of the vast discrepancy between the alimentary and inhalation doses necessary to produce infection. Jallin (*Zeit. f. Hyg.*, Bd. 60, H. 3) answers the theories of the Lille school that foreign bodies, such as bacilli, cannot reach the lungs by inhalation but only after absorption from the alimentary canal. He also determined the part of the lungs, the finer bronchi or the alveoli, in which bacilli were detained. He used the spores of an easily recognizable mould. The spores were blown into the air and breathed by guinea-pigs, which were killed at different intervals after the inhalation. With *Aspergillus fumigatus* spores the results were as follows: After inhalation for half an hour the animals died from dyspnoea in seven or eight hours. The lungs were filled with haemorrhagic foci. Spores were found in mucus and in plate cultivations from the lungs. Microscopically they could be seen in the alveoli and smaller bronchioles. Smaller doses were used. After three hours the spores were found in the alveolar walls as well as in the alveoli. After six hours they were almost all within the alveolar wall. After longer intervals they were proliferating and finally there was cellular infiltration. *Aspergillus niger* was then tried as it was less injurious. The results were similar, but there was less inflammatory reaction. With the harmless spores of *Penicillium glaucum* identical results were obtained in so far as the spores passed into the alveolar wall just as rapidly. Control feeding experiments were performed. The animals were fed on large quantities of the spores for seven to fourteen days, but the spores could not be found in the lungs, either by cultivation or by simple microscopic examination. HEYMAN (*Zeit. f. Hyg.*, Bd. 60, H. 3) examined the lungs of guinea-pigs at different intervals after the inhalation of known quantities of tubercle bacilli. In a first series of researches the portions of the lungs to be examined were inoculated into a second series of animals. After inhalation of 10,000 or 100,000 bacilli the bacilli could be demonstrated in the most peripheral parts of the lungs after one hour, whilst they could be found in the glands only after three days. After inhalation of 1,000,000 the bacilli could be demonstrated in the lungs and in the bronchial glands from the first. Using microscopic methods alone, he could demonstrate bacilli only after inhalation of 1,000,000. After two hours they were found in the epithelial cells of the finer bronchioles, in degenerated alveolar epithelium, in the alveolar wall, in the epithelial cells under the bronchial epithelium, and, rarely, free in the alveoli. It is noteworthy that he rarely found them inside the leucocytes, either free in the alveoli or in the alveolar wall. Oettinger (*Zeit. f. Hyg.*, Bd. 60, H. 3) discusses the predisposition of the lungs to tuberculosis. Whether the infection be due to intravenous or to alimentary infection the disease is usually in the lungs. A satisfactory explanation that the lungs act as a filter has not been satisfactorily demonstrated. Vastenburg's experiments, where he found carbon particles in the lungs after feeding on scot through a stomach tube, are rejected on account of the difficulty of avoiding inhalatory contamination in this method. *A priori*, there are objections to this mechanical explanation, for the lung capillaries are very wide, and the velocity of the blood in the lungs is very high. It has been shown that intravenous injection of carbon particles leads to pigmentation of the liver and spleen as well as the lungs. Oettinger injected small quantities of different organisms into the arterial vein of rabbits, killed the animals, and then estimated the number of bacilli in the different organs by rubbing up a small portion of the organ in broth and plating. In order to imitate the natural conditions of rupture of a tuberculous gland into a vein, he also used an agglutinated culture of *B. typhosus*. In all cases he found that by far the greater part of the bacilli were found in the liver. With the agglutinated organisms he found a much larger proportion of them in the lungs, but never so many as in the liver. He next attempted to obtain roughly quantitative results with tubercle, using inoculation of a second series of guinea-pigs as a quantitative test. He showed that the bacilli were found in all the organs, but as he never reached the sublethal dose his results here are incomplete. Having thus shown that mechanical factors will not explain the predisposition of the lungs to tubercle, he calls attention to Neumann and Wittenstein's work. These investigators injected dogs intravenously with tubercle bacilli, killed the dogs, and then estimated the infectivity of the lungs and other organs (1) immediately after death, and (2) after the same organs had been kept for twenty days. In the first case "all the organs were infective," but after twenty days "all but the lungs were harmless." KOLSON (*Zeit. f. Hyg.*, Band 60, H. 3), noting that other investigators had obtained conflicting results from experi-

ments on the inhalation of dried sputum dust, performed some very careful quantitative experiments. He knew the amount of air inhaled in a given time by a guinea-pig. Then, using some easily recognizable spores which could be cultivated and enumerated on plates, he placed a guinea-pig in an infected atmosphere for a certain time, killed it, and estimated the number of spores in the lungs. This number is called L. From the same atmosphere at the same time he sucked the same amount of air as would be breathed by the animal through a filter paper, and then estimated the number of spores on the filter paper (Number F). With great care he found the ratio L:F fairly constant. It varied from 4 to 10 per cent., the average being 7 per cent. Findel, working with a moist spray, had found the ratio to be about 33 per cent., showing that moist bacilli were more readily retained than dry ones. With some dust from a local cotton factory he then made a mixture containing known numbers of both spores and tubercle bacilli. Thus 8 grams of dust contained 90 million spores and 11 million tubercle bacilli to the cubic centimetre. With this mixture he performed fifteen experiments. From the above data he was able to determine that number of bacilli which, inhaled with dust, were sufficient to cause an infection. It was found that to get constant results it was necessary to use 300 to 400 bacilli. In one case a dose of 50 was sufficient. With the moist spray 50 bacilli are always fatal, whilst 5 or 6 are often fatal. With dried sputum dust mixed with dust from a dwelling he found that the dose was 300 to 4,000 bacilli, whilst the same sputum used for a spraying experiment gave uniform infection after the inhalation of 50 to 60 bacilli. It seems probable that bacilli inhaled with dust are more readily removed by the cilia of the bronchial passages. Natural conditions were then imitated. Guinea-pigs were placed in a cage at different heights from the floor, some sputum rubbed up with street dust to a fine powder was then placed on the floor and stirred up with a broom every ten minutes for half an hour. Most of the animals suffered from pulmonary tuberculosis. Kölsch thinks that these conditions were, however, worse than ever obtained in a dwelling. He wished to try the effect of letting the animals inhale the dust in a dwelling where there was pronounced expectoration. Thanks to the spitting regulations, he was unable to find such a house in Breslau. Experiments with the dust from very dirty houses were negative, even after two hours' inhalation. He concludes that infection from the inhalation of infected dust is possible under certain conditions—namely, dryness of the dust and inhalation of very large quantities.—Ostermann (*Zeit. f. Hyg.*, Bd. 60, H. 3) deals with the question of contact infection, especially in children. Tuberculosis in the first year is very common. Direct infection through kissing and "dummies" is not probable, owing to the spread of the knowledge of the infectious nature of tubercle. Great importance has been attached to the so-called "Schmutz" or smut infection. The child in crawling about contaminates its fingers and transfers the bacilli to its mouth. Ostermann carefully investigated the conditions in the houses of twenty infected families where the conditions were exceptionally bad even for Breslau, a very dirty town. Of 42 children examined bacilli were found by injection of washings into guinea-pigs in 4 only. Examination of the floors gave results in 50 per cent. He thinks this proportion very small when the extreme filthiness of the houses is taken into consideration and in connexion with other researches by fellow-workers thinks that they indicate the rarity of "Schmutz" infection. Investigating adults, he examined the hands of 14 consumptives, finding the bacilli on 7; also on the hands of one healthy nurse. Are these transferred in handshaking, etc.? The spores of a harmless saprophyte were rubbed on the hands of one person and allowed to dry. His own thumb was then rubbed on the infected palm, the organisms washed off his thumb and plated. At the most only 1 out of the 700 spores were transferred. A rich tuberculous sputum was then dried on one hand and a second hand vigorously rubbed on the infected hand. The washings of the second hand were injected into guinea-pigs with negative results in every case. Is the nose or mouth likely to be infected from the infected second finger? A finger-pad was infected with a known number of spores, then immersed with a slight rubbing movement in broth, which was subsequently plated. The time of immersion was found to be a most important factor. For one second 1 to 500, 1 to 343, 1 to 9, and 1 to 8 were the maxima in a series of experiments. He sums up the possibilities of contact infection in adults as follows: There might be a thick layer of dry sputum on a consumptive's hand; a healthy person by a long and

heavy grasp might transfer some to his own hand; he might then suck it off his fingers into his mouth—all remotely possible but highly improbable. In a second paper Ostermann discusses the danger of milk infection. By inoculating guinea-pigs with varying dilutions of milk from cows with udder tuberculosis, he estimated that the worst "single cow" milk he could find had about 10 to 20 bacilli in $\frac{1}{1000}$ c.c.m. One such cow in a herd would cause the milk to contain at least 1,000 bacilli to the cubic centimetre. That this is an extreme case is shown by the fact that only 10 per cent. of the market milks are infectious to guinea-pigs. With 1,000 bacilli to the cubic centimetre in the milk, the butter from the same herd would contain about 100 to the gram. Is such milk dangerous to the human child when taken into the alimentary canal? Findel, Reichenbach, and Alexander have determined the minimum fatal alimentary dose for the guinea-pig: 140,000,000 is the minimum for the guinea-pig when taken in one dose; when the dose is repeated fifty times the minimum is 800,000. Then assuming the consumption of 1 litre of milk with 1,000 bacilli to the cubic centimetre, we get a daily dose of 1,000,000, which is harmless in a single dose, and only just on the borderland of danger when fed to a very susceptible animal like the guinea-pig. The butter would certainly be harmless. He concludes that the danger from milk is very slight. He does not claim that dairy inspection is unnecessary (he admits its necessity for other reasons), but he claims that we must not expect great improvements from these measures alone. They will do harm if they lead to the neglect of other more important measures.—Bruno Heymann (*Zeit. f. Hyg.*, Bd. 60, H. 3) discusses the relation of infant's tuberculosis to milk. His arguments are derived from statistical and ethnographic data. The cases of infection of wounds from bovine tuberculous products, although many have been recorded, are not of importance. Compared with the frequency of opportunities for infection they are very rare. As regards primary intestinal infections, these are very rare, according to many leading German pathologists. The English statistics which make it much commoner are not reliable, for many cases of enlarged mesenteric glands are not tuberculous, yet are, he claims, counted as such. The English and German communities, who were specially looking for bovine cases, isolated altogether 271 strains, of which only 39 were bovine. Caffky, out of 57 consecutive cases in children, found only 2 which were bovine. Beitzke, in 25 cases of children's tuberculosis, found 2 bovine. All pulmonary cases are due to the human bacillus, and when it is remembered that in Germany there are 108 deaths due to pulmonary tubercle to 10 from tubercle in other organs, the overwhelming importance of human sources of infection is manifest. Investigation of families where tuberculous milk has been consumed for long periods fails to make out a case for the bovine bacillus. Out of 53 cases there was found 1 case of undoubted bovine infection and 3 very doubtful ones. Raw has stated that in countries with a large consumption of raw milk there is an increased incidence of surgical tuberculosis, which he assumes to be due to the bovine bacillus. Heymann criticizes this argument from two standpoints: (1) Most surgical tuberculosis is of human origin. Oehlecker investigated 50 consecutive cases of surgical tuberculosis, and found only 4 to be of bovine origin. (2) He quotes some countries where no milk is consumed but tuberculosis is very common. *Japan*: (Kitasato) *Perlsucht* only introduced thirty years ago, whilst tubercle is very common. Children never get milk, yet alimentary tuberculosis is very common. *Greenland*: No tuberculous milk, yet phthisis very common, and tubercle meningitis one of the commonest causes of death in children. *Asiatic Turkey*: Raw milk never drunk even by adults, children breast-fed for two years; tuberculosis of all kinds very common and very virulent. *Roumania*: Children breast-fed for a very long time; tuberculosis very rare even in regions where there is no milk at all. *Faroe Islands*: *Perlsucht* only introduced a few years ago; tubercle of all kinds very rare for a long time. Out of 342 cases the infection could be traced to human infection in 262. *Egypt*: Milk so dear that it is a luxury to the rich; tuberculosis very common, especially amongst the negroes and Berbers. It is only necessary to see one Berber expectorate to understand why it spreads so well. *Gold Coast*: Children breast-fed or on a concoction of palm oil; tuberculosis of all kinds rare. Heymann comes to the conclusion that the great prevalence of human tubercle cannot be due to *Perlsucht*, but must be due to some other cause, and that our endeavours to combat the main source of infection must not be abated by a sense of security based on rigid milk and meat inspection.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

24. Pressure Pain, a Symptom of beginning Consumption.

THE pathological increase of the painful sensation on pressure is a symptom which K. Francke (*Bett. z. Klin. d. Tub.*, vol. X, No. 3, 1908) wishes to employ in the diagnosis of the early stages of pulmonary tuberculosis. He has directed the attention of clinicians to this phenomenon in an article entitled "Algeoscopy" in 1901, but up to the present but little attention appears to have been paid to the subject. He points out that since the lung tissue itself is poor in sensory nerves, it cannot be expected that inflammation of the lung in itself will produce pain. Tuberculosis of the lung usually begins at the apex, close to the pleura, and the inflammation passes over to the visceral layer of the pleura at an early stage. Soon the parietal layer is affected; roughness of the surfaces follows and friction is produced. Adhesions are not uncommon and these give rise to dragging. In this way pain is produced in connexion with early pulmonary tuberculosis. Based on his observations made in the post-mortem room, he states that the beginning of the lesions is to be found behind and close to the top of the apex, and not in front. In the early stages pain in this situation is rarely spontaneous, and is not severe. Pain on sneezing, coughing and breathing speak for advanced lesions. However, pain is experienced in the earliest stages when the part affected is pressed upon. The cause of the pain may, of course, be something else besides tuberculous pleurisy, but the differential diagnosis is not difficult. He finds that there are three methods of utilizing pain diagnostically: (1) observing if the patient complains spontaneously of pain; (2) questioning whether he has pain; and (3) testing for pathological pain pressure areas. For the early diagnosis of consumption only the third method comes into account. Pressure on normal tissue is not painful or even unpleasant, while it becomes definitely painful when the tissue pressed is pathological. When the pressure is an increasing one, pain is usually complained of. The patient may call out, or he may simply wince or draw up his face, or he may move away to avoid the continuance of the painful pressure, or, in the case of a lung, he may begin to cough. The pressure may be exerted by a percussion hammer, or by the fist or by a finger. The author has designed a special hammer, which he considers to be better than all other percussion hammers. This instrument is used for the purpose. The fist, he states, is also a useful means of eliciting the pain from pressure. When applied by the finger, he calls the method algeoscopy, and this method he finds to be the most delicate. After discussing the situations at which the pain is found in phthisis, he turns to the exclusion of other conditions. Rheumatic muscle pains are limited to groups of muscles and the distribution suffices to distinguish them. Neuralgias can also be detected by their distribution. It is extremely rare that a costal neuralgia is limited to the first or second cervical nerve on one side. He also deals with less common diseases, and concludes by describing briefly his method of testing for pressure pain. This is done by gradually applying pressure and desisting as soon as the pain is determined. He finds that this symptom is present in 81 per cent. of all early cases. The symptom alone is not supposed to form the basis of the diagnosis of phthisis, but in conjunction with other signs it will be found of great value.

25. Sigmoiditis and Perisigmoiditis.

A. MAYOR (*Journ. de Méd. et de Chir.*, July 25th, 1908) divides sigmoiditis into chronic and febrile forms, and then discusses perisigmoiditis. Chronic sigmoiditis occurs usually in persons the subject of chronic constipation. Patients the subject of this disorder complain of pain in the left iliac region, which is intensified before or after defaecation; movements of the body increase the pain. Complaints are also made by these patients of functional intestinal troubles, and sometimes attacks of "diarrhoea" occur, the motions being glairy and even bloodstained. Loss of appetite and often great loss of flesh occur after a time. On palpating the left iliac fossa, one finds a cylindrical, elongated, sausage-shaped swelling, which is firm to the touch, and which gradually tapers off above into the descending colon. In febrile sigmoiditis two

classes of cases are met with. In one variety occur cases of definite inflammatory trouble, but the inflammation appears to be too superficial, and arises too quickly for one to consider that the whole thickness of the gut has been involved. In these cases purgatives and enemata cause a complete subsidence of the signs and symptoms in a few days. In the other variety of sigmoiditis the whole thickness of the gut is involved, and sometimes this occurs in a case of chronic sigmoiditis. In most of these cases, however, the patient has suffered only from chronic constipation until more or less suddenly pain in the left iliac region sets in. These pains may remain localized or may radiate to other parts, such as the bladder, and in a few days' time become very marked, disturbing and preventing sleep. The temperature is raised, nausea and sometimes vomiting occur, and the constipation may indeed become absolute, neither faeces nor flatus being passed. Sometimes, however, there may be diarrhoea. Accompanying these symptoms one finds some abdominal distension, and on palpation a similar mass to that found in chronic sigmoiditis is to be detected in the left iliac region. In a few days' time, under suitable treatment, the acute symptoms subside, and flatus and faeces are passed, but the passage of these causes marked pain in the iliac region. Perisigmoiditis occurs in two main forms. In the first the affection occurs in persons who suffer from sigmoiditis. In these cases fever sets in, sometimes with shiverings; nausea and vomiting, which become more and more frequent, occur; general abdominal distension, with absolute constipation, sets in, and muscular rigidity over the left iliac region becomes more marked. These symptoms, together with the changes in the pulse and the faeces, cause marked resemblance to a case of general peritonitis. In the course of a few days one finds in the left iliac region a large swelling. When resolution occurs the sigmoid loop gradually separates itself from the surrounding loops of gut and appears hard, sausage-shaped, and painful to pressure. If suppuration occurs, the usual symptoms of suppuration show themselves, and the swelling gradually increases in size. In the second variety of perisigmoiditis the patient may be suddenly attacked whilst in the best of health; in other cases he has suffered from intestinal disturbances for some time previously. In both cases, however, the symptoms of perisigmoiditis very quickly show themselves, either in the form of an iliac phlegmon or in the form of a peritoneal inflammation. In these cases of abrupt onset the thigh may be flexed on the pelvis or pains may be felt in the left leg. Of the complications which may arise from sigmoiditis and perisigmoiditis, Monod mentions transitory albuminuria, phlegmasia is noted by Loison, a pain over the liver on percussion by Mayor and Gerlier. In some patients their constipation becomes aggravated, and in others defaecation is always accompanied by pain. Recurrences are relatively frequent. Simple chronic sigmoiditis has to be differentiated from cancer or tuberculosis of the sigmoid. Where in addition acute attacks have occurred, actinomycosis and inflammation, consecutive to intestinal narrowing, have to be considered. When suppuration has occurred, infections of the female genital organs, appendicitis and abscess of the psoas muscle have to be considered in the differential diagnosis. The greatest difficulty is to exclude cancer; but where there is a definite history of several years' duration, and in the course of which one discovers in the left iliac region a cylindrical sausage-shaped swelling, which is quite regular, smooth, mobile, and firm, but not of a wooden hardness, and when one finds that there is no history of frequent attacks of diarrhoea, or of abundant haemorrhages, one can with considerable confidence exclude cancer. As regards treatment of these conditions, the main endeavours are to overcome constipation, to relieve pain, and to favour resolution of the inflammatory trouble. When there are no marked peritoneal signs daily purgation is indicated. Injections of warmed oil are useful, and for the relief of abdominal pain hot fomentations are of great use. At the commencement of an attack of perisigmoiditis a small dose of morphine should be given to relieve any intestinal spasm, whilst treatment is conducted on similar lines to those employed in sigmoiditis.

26. A Scapular Murmur.

UNDER this title Tedeschi (*Gazz. degli Osped.*, November 8th, 1908) describes certain phenomena which can

he detected in some cases when the palm of the hand is laid over the scapula and the patient told to breathe forcibly or swing the arm to and fro. Under these conditions something between a thrill and a friction fremitus can occasionally be detected, or if the ear is placed over the spot a sound between a rustle and a bubble. Continued movement of the arm may cause the sensation to disappear. The sensation described is not to be confused with pleural friction or with coarse rheumatic grating. During the last three years the author has observed 58 cases where this scapular murmur could be detected: 32 of these presented early signs of phthisis either at the time or shortly after the detection of the murmur: 17 had decided, rather advanced phthisis; and 9 showed nothing more than anaemia and general debility. There was no constant relation between the diseased lung and the side where the scapular murmur existed; sometimes it was the same side and vice versa. It could not be due to wasting of the shoulder muscles, for in the early cases there was no wasting. Exaggerated professional use of muscles (for example, in seamstresses) might tend to cause this particular localization, but the leading factor seems to be tuberculosis, and the author believes it is really a case of tuberculous myositis. The chief aim, however, in bringing the matter forward is because it may be of assistance in the early diagnosis of phthisis. The author says that he has not infrequently detected this scapular murmur before the appearance of any recognizable clinical signs of that disease.

SURGERY.

27. Prostatectomy.
WILMS (*Deut. Zeit. f. Chir.*, Bd. 93, Hn. 4 and 5) states that though suprapubic prostatectomy is rapidly superseding the perineal operation, he still, with many of his German colleagues, prefers the latter, the general adoption of which, he holds, is prevented only by the dread of wounding the rectum. It is asserted that the diseased prostate, even though it may not be much enlarged, projects downwards at the margins of the pubic arch to such an extent that either of its lateral lobes can be readily reached through an incision made on the corresponding side of the perineum. This incision, which should be about 2 in. in length, is made over the descending pubic ramus on the left side. After blunt dissection of the thin layer of fascia and the subjacent layer of connective tissue, the left lobe of the prostate is reached. In the deep dissection the ischio-cavernosus muscle, together with the internal pudic artery and its branches, is pressed towards the middle line. After the course of the urethra has been revealed by the introduction of a catheter, and the capsule of the left lobe of the prostate has been incised, the operator will be able on introducing his finger through this opening to separate the whole of the prostate from its capsule as is done in the vesical method. The right lobe should be first attacked in front, where there is often some resistance to be overcome at the junction of the two lobes. The prostatic portion of the urethra is removed with the gland. In his experience of this operation the author has been struck by the small amount of bleeding. Wounding of the rectum is, it is held, quite impossible, as in detaching the posterior part of the gland the surgeon works within the capsule. In the after-treatment inferior drainage is carried out. The author, who has been led by the results of his own experience to prefer this method of prostatectomy to any other in present use, hopes that its simplicity and efficiency will soon be widely recognized.

28. Cholesteatoma or Umbilical Calculus.
COENEN (*Beiträge zur klin. Chirurg.*, vol. lviii, Part 3, 1908) reports that a porter, aged 49, was admitted into hospital for a suppurating umbilical fistula. He was of intemperate habits, yet had enjoyed good health until the past six months. Then pain in the umbilical region set in, especially when he bent his body at work. Three days before admission pus and blood discharged freely from the navel. There had been no symptoms of peritonitis. Coenen found that the discharge was very free and feculent, so that intestinal fistula was suspected, but no trace of semidigested food tissue could be detected. Around the fistula there was redness of the skin and induration with tenderness. Icterus set in a day or two after admission. A free incision was made over and through the orifice of the fistula, exposing a cavity filled with pus, of the capacity of a hen's egg. It extended posteriorly into the abdominal cavity, but was cut off from the peritoneal cavity by old peritonitic adhesions. In the abscess cavity lay a pearly,

shining body as big as a pigeon's egg. On section it was seen to be laminated; in fact, it was a cholesteatoma. The jaundice disappeared a few days after the operation, and the fistula healed up. The complication, according to Coenen, was therefore not due to hepatic disease, but to pressure of the wide area of inflamed parietal tissue and of the abscess on the bile ducts. He adds that new growths are relatively common in the tissues of the umbilicus. Again, fistulae communicating with Meckel's diverticulum and the trachus, and fistulous tracts lined with gastric mucous membrane (Tillmanns, Lexer, etc.), as well as urachal cysts, have repeatedly been detected in connexion with the umbilicus, as well as small new growths representing inclusion of intestinal epithelium.

29. Molluscum Contagiosum in Husband, Wife, and Child.

GOODALL (*Amer. Journ. Obstet.*, September, 1908) was consulted by an emigrant French woman in the fifth month of pregnancy for frequent micturition. He found no definite condition which could explain the symptom, and there was no abnormality about the genitals. Two months later the husband consulted Goodall on account of an attack of molluscum on the dorsum of the penis, partly suppurating. The only explanation which he could give was that when on board ship he had frequently used towels in common with other passengers. The first wart, as he called it, appeared over three months after he had landed with his wife in Canada. He had irritated the nodules of molluscum by caustics. Two small nodules appeared on the mucous surface of the prepuce. He was advised not to have connexion, and when he brought his wife at a second visit not a trace of the disease could be found on the external or internal genitals. She was delivered at term about two months after that visit, and not a sign of molluscum was detected. Two months after the confinement she consulted Goodall once more, stating that she thought she had contracted the disease to which her husband was subject. Nineteen characteristic nodules were found, confined to the labia majora, perineum, region of anus, and outer surface of the labia minora. Eleven months later the mother brought her child, which had developed seven nodules of mollusca on the left side of the neck and shoulder. They had been observed by the mother for about six weeks. Although the symptoms of the skin disease in the child developed late, and although Goodall detected no trace of molluscum on the mother's genitals during delivery, he was inclined to believe that molluscum was incipient in the mother at that time, and that it was then communicated to the infant in whom it lay latent for several months. Goodall dwells on the fact that in the case of the mother no trace of molluscum could be found on the cervix, vagina, or mucous surface of the vulva. The bactericidal action of the genital secretion prevented infection. The absence of sebaceous or other glands in the vagina has to be taken into account, but glands exist on the inner surface of the labia minora and in the vestibule.

OBSTETRICS.

30. Caesarean Section.
MOUCHOTTE (*Ann. de Gyn. et d'Obstét.*, November, 1908) reports 14 cases in which Caesarean section was successfully performed. He found that in 12 out of the 14 cases the pelvis was rachitic with markedly reduced diameters, seven pelves belonging to the canaliculated type, and five to the annulated type. In dealing with contracted pelvis, he waits for dilatation to become complete in order that symphysiotomy may be attempted; but when symptoms of urgency arise, Caesarean section is undertaken without further delay. In two of his cases prolapse of the cord and a change in the cardiac sounds hastened intervention. In two others a brow presentation showed signs of becoming impacted, and in two other cases osteitis and tuberculous hip had caused obstruction of the parturient canal. Operation was only undertaken after the onset of labour pains. In cases which evidently cannot be delivered naturally there is no need to delay operation for long; in cases of moderate contraction, when there is some hope of spontaneous delivery, the practitioner may wait some hours, even some days, for complete dilatation followed by symphysiotomy. If while waiting signs of distress on the part of the mother or child supervene, the operation cannot be deferred, and is then undertaken under less favourable conditions. Nine of the writer's cases were operated upon late, and after the membranes had ruptured, and it was in these cases that a rise of

temperature and in the pulse-rate was noted during the two subsequent days. In all the operations the uterus was brought out of the abdomen before being incised; this method is considered to conform more particularly to surgical principles, and to prevent the entrance of blood or fluid into the peritoneal cavity. If gloves are worn they should be changed after the uterus has been cleared out and cleansed. Vertical incisions were made in the middle line, beginning below at the junction of the lower and upper uterine segments. It is not unusual to find the placenta adherent to the anterior uterine wall, and in the line of incision. In the earlier cases the incision was made through the placental tissue, but this plan was abandoned in favour of finding the layer of attachment of the placenta to the muscle wall and stripping it up, so as to permit of incision of the wall; the membranes were then divided above the placental margin, and the fetus having been extracted, it was simple to remove the whole after birth intact. The cleansing of the uterine cavity is accomplished rapidly, unless there is adherence from endometritis. This was present in two of the cases reported; one suffered from phlegmasia dolens and fetid lochia, the other had a small haemorrhage. A gauze drain put into the uterus before suturing and led out through the os uteri assists drainage, but is unnecessary when the membranes have not been ruptured before the operation. Catgut was used for sutures, and in all cases a drain was left in the abdominal wound for forty-eight hours. The writer considers the operation a simple one, easy to execute, and giving excellent results.

31. Caesarean Section in Cases of Vaginal Contractions.

POZZI and HARTMANN (*Comptes Rendus de la Soc. d'Obstét. de Gyn. et de Pédiatr.*, July-October, 1907) related two instances where Caesarean section was performed on women with contractions of the vagina. Pozzi's patient was a healthy married woman aged 23. She had menstruated ever since the age of 17, and married at 18; connexion was always painful. At length, when under observation, she became pregnant. The meatus urinarius was not quite normally placed; the vagina ended in a cul-de-sac about 2 in. above the vulva, where the os externum could be felt as an orifice with rigid borders, about 1 mm. in diameter, and not dilatable. As the cervix was softened by gestation its limits could not easily be defined. About term it was found that the fetal heart sounds were becoming weak, so Pozzi did not wait for labour. He performed Caesarean section, saving both mother and child. As he found that it was impossible to drain the uterine cavity through the vagina, owing to the rigidity of the contraction, he amputated the uterus above the cervix. Hartmann's patient was 39 years old. When 25 years old she suffered from dysmenorrhoea; her doctor then discovered a vaginal contraction, through which only a very slender probe could be passed. Some operation, of a nature not clearly ascertained, was performed, and the catamenia were never painful afterwards. In 1905 the patient consulted Hartmann, and he could define a circular stricture 1½ in. above the fourchette; the forefinger could hardly be passed through it. He did not advise any operation, and considered that there was little chance of pregnancy; though, if it occurred, delivery through the natural passages seemed hardly possible. The patient did become pregnant, the vagina grew softer and more capacious, but the stricture remained as narrow and rigid as before. Labour pains set in about term. Hartmann operated, saving mother and child. As in Pozzi's case, the stricture prevented drainage, and the dangers of another pregnancy seemed great; moreover, the patient was relatively old. He therefore amputated the uterus above the cervix. There was a long discussion after the two cases were read before a medical society, in which several leading obstetricians took part. A few details were criticized, more than one speaker implying that the uterus in both cases might have been saved, a second Caesarean section being hardly more dangerous than a first; but Pozzi insisted on the unfavourable condition of his case for vaginal drainage, so that infection would have been almost certain; and Hartmann stated that his patient, nearly 40 years of age, lived in a remote country district, and might therefore be in danger, for self-evident reasons, should she become pregnant once more. Lepage doubted if all chance of further offspring should be taken away; the only child in both these cases might die. Pinard favoured operations of this kind when labour set in, and not earlier. Operators made too sure about "term" when there had been no pains. Routier related a case where labour was retarded by a cicatrix following sloughing of the vulva and part of the vagina as

a complication of small-pox. The scar tissue, however, was successfully divided with scissors, and the child was delivered alive. Potocki operated in 1902 in a case of congenital stricture during labour, after finding that the firm circular ring half-way up the vagina was not stretched by the pressure of the fetal head during the pains. He performed Caesarean section, and amputated the body of the uterus. The patient recovered, and suckled her child.

GYNAECOLOGY.

32. Bier's Method in Gynaecology.

ADLER (*Pester Mediz.-Chirurg. Presse*, November 8th, 1908) has found Bier's method of value in cases of old and obstinate endometritis, the secretion disappearing permanently for a long time; in cases of inflamed appendages, the pain being always stilled while exudation is not appreciably lessened; and in amenorrhoea. His cases of endometritis were those which had been under treatment on and off for two to five years without essential improvement. He applied suction daily, or every other day, for five to fifteen minutes, with moderate rarefaction. After the first sitting the secretion was much increased; after four or five sittings discharge ceased; and in three to six weeks the patients were cured. Some returned after several months with a slight discharge. Erosions were often present and healed slowly—in one or two months. There was no pain during the suction, or if present it ceased at once on letting a little air in. In no case did considerable bleeding result. In cases of subacute and chronic inflammation of appendages with exudation, Adler found that though pain was removed the exudation was but slightly influenced. In 3 cases of large exudation of puerperal origin in private practice the treatment was begun ten to fourteen days after the fever, and was continued, at first daily and then every other day, for five to six weeks, but the exudation was only reduced by a quarter or a third. The result in chronic tumours of the appendages was no better. In 8 cases no cure resulted, but after four or five sittings pain began to lessen, and later disappeared, while in three or four weeks the patients mostly felt well. In 4 cases of retroflexion with fixation, in private practice (other means being also employed), the author had the impression that the suction was of definite assistance. A hypoplastic uterus was treated on account of amenorrhoea for two months every other day. A sufficiently copious period, quite painless, lasting two days, ensued, while a decided development of the uterus took place. Adler uses the ordinary tube speculum of caoutchouc, which is closed after insertion in the vagina (the cervix being carefully introduced) by a conical rubber stopper, pierced by a glass tube which is connected by a rubber tube with the pump. When the required rarefaction is obtained this rubber tube is clamped and the instrument left on for a certain time. The speculum is only removed when the cork has been taken out. The action of the suction is partly the regular removal of the secretion, partly the hyperaemia induced on the pelvic organs, and partly the congestion caused by the kinking of the veins.

THERAPEUTICS.

33. Unna's Bandage in Ulcers of the Leg, etc.

HECKER (*Mediz. Klinik*, October 18th and October 25th, 1908) has employed Unna's paste since 1886, and finds Unna's original formula the best—that is, zinc oxide, gelatin, aa 4 parts, glycerini, aq. destillat., aa 16 parts (ichthylol 1 part). The leg is thoroughly cleansed with soap in a warm bath, shaved, and the fat removed by rubbing with cotton-wool dipped in ether or benzine. The whole of the leg except the ulcer is then painted by a bristle paintbrush with Unna's paste liquefied (but not heated) in a water bath. The ulcer is sprinkled over with a thick layer of airoil and covered with cotton-wool, which is also placed round the foot immediately behind the toes and around the leg about a handbreadth below the knee. The heel and ankle are covered with cotton-wool or, in very sensitive people, with boletus igniarius. Two strong gauze double-headed bandages (that is, rolled from both ends towards the middle to get the necessary pressure) are well wrung out of water and applied, if possible, before the patient leaves bed. The leg is banded from the ankle to the toes and upwards to a handbreadth below the knee, the cotton-wool reaching a centimetre higher, each turn of the bandage overlapping the previous one. The second bandage is similarly applied over the first, every turn being drawn equally tight. The leg

must be kept horizontal throughout, and the bandage freely exposed to the air until fully hardened. This may be hastened by a hot stove or the sun. Unna's bandage should be worn some time after the ulcer heals, and be followed by an elastic bandage until the scar is quite consolidated. Hecker leaves the bandage on three weeks, or, later, four to six weeks, more frequent changing being only necessary in cases of unusually free secretion. Some accumulation of secretion does not in any way hinder the cicatrizing of the ulcer if a thick layer of aïrol, dermatol, or xeroform be present. With these Hecker has never observed idiosyncrasies, as in the case of iodoform. The bandage is cut away with plaster-of-Paris nippers or simply unwound after softening with warm water, the outline of the ulcer having been sketched on the bandage as soon as hardening occurred. If the surrounding skin is much irritated, before applying the bandage rest and compresses of lead acetate, lysol, chinolol, or those with ice, may be used for three or four days. If eczema still persists, spreading it with Unna's paste usually suffices to heal it. In cases of bad weeping eczema, first apply Lassar's paste (zinc oxide and starch in 1. vaseline 2). The chief advantages of Unna's bandage are: (1) Rapidity of healing, a firmer cicatrix being formed than by any other method after a few bandages; (2) the patient's occupation may be continued undisturbed throughout; (3) enormous saving of expense; (4) if the bandage presses in any place, it may be permanently softened by repeated moistening, instead of cutting it away; (5) the severe pains accompanying ulcers of the leg diminish and disappear; (6) the bandage has a good effect on varicose veins. It is best to first paint these thickly with ichthyol-collodium, 1 to 10. Unna's bandage is also very useful in promoting (1) the absorption of effusions into joints, (2) the healing of wounds. It is very practical for children, round the neck (after extirpation of glands, etc.), thorax, limbs, especially where these join the trunk, and fingers. After an amputation or excision, etc., the wound is covered with a thick layer of iodoform gauze, a few turns of a small bandage applied, and the whole finger enveloped in paste. The simple method of arresting hæmorrhage by means of this bandage forms an important substitute on the battlefield for the dangerous and painful tourniquet.

34. The Prevention of Tuberculosis in Childhood.

S. A. KNOPE (New York *Med. Record*, December 5th, 1908) says that the predisposition to tuberculosis consists of a general enfeebled condition without distinct pathological lesions, all the organs possessing less than normal resistance to the attacks of disease. The overcoming of this predisposition must begin *in utero*, the mother being placed in the best possible hygienic conditions while bearing the child. She should take breathing exercises. Her living and sleeping rooms should be well ventilated. There should be a law preventing work in dusty, insanitary environments for children, and a pregnant woman should have to give up work in a shop two months before her confinement. The newly-born child needs fresh air as much as the mother. From the tenth to the twelfth months the child should be accustomed to cold baths gradually. Children should be dressed without constriction and young girls without the corset. The author describes exercises to be used to produce deep breathing. The conception of deficient respiratory function in the apices is erroneous. These portions of the lungs inspire well but expire poorly, so that the micro-organisms remain in them. A thorough inhalation followed by a thorough exhalation should be taught by exercises. The child should not go to school before the eighth year. It should have more sleep than other children, and should be most of the time in the open air during the day. More school farms and playgrounds are needed, and outdoor sports should be encouraged. The most frequent sources of post-natal infection are kissing, tasting the food, coughing in the face of the child, and the infection of its hands by handling articles and playing on the floor. Ritual circumcision should be placed under sanitary restrictions.

PATHOLOGY.

35. Human and Bovine Tubercle Bacilli.

IN from 1 to 5 per cent. of phthisical patients either no or but few tubercle bacilli can be found in the sputum when stained by the usual Ziehl method, but when the sputum is stained by Sprengler's "*Pertsucht*" method numerous bacilli may be seen. C. Sprengler (*Deut. med. Woch.*, February 28th, 1907) finds that bovine bacilli are easily decolorized by acid, especially when found in the human host. His method is carried out without any acid treat-

ment. He further has found that nearly 60 per cent. of all phthisical patients have both the human and bovine type of bacilli in their sputum. He therefore came to the conclusion that it was very desirable to work out a more certain method for distinguishing between the two forms of tubercle bacilli by means of staining properties. He now describes three new methods. First, he deals with his capsule or envelope method. This is a method of staining in layers. Smears are rendered alkaline in a 1 per cent. caustic soda or potash solution and very carefully dried with heat. The wax envelope of the bovine bacillus has a low melting point, and therefore one must be careful not to overheat. Next one pours on to the specimen some Loeffler's methylene blue, and washes with water. The next stage consists in staining with warm carbol fuchsin until steam rises from the fluid, and then washing off the stain with water. Then one restains with methylene blue and adds one or two drops of a 15 per cent. sulphuric acid to the stain. This stage only lasts a few seconds. The specimen is then rinsed in water and dried between blotting paper or by some other means, care, however, being taken not to overheat if dried over the flame. Stained in this way, *Pertsucht* bacilli appear much larger than human tubercle bacilli. Another striking difference between the two forms when stained by the capsule method is that the bovine bacilli show what Sprengler calls "*splinters*," which are structures arranged in the interior of the bacillus in a precisely similar manner as anthrax spores are arranged. He claims to have proved that these splinters are spores. In the human bacillus no such splinter formation is seen, while spore-like bodies which are arranged in chains are seen instead. The wax capsule is very thin, and constricts the bacillus between the spore-like bodies. The wax capsule is rarely sharply defined in the latter, but it is always sharply defined in bovine bacilli. The envelope method only succeeds satisfactorily when the *Pertsucht* bacilli have not been subjected to drying. The envelope is very delicate, and is liable to shrink when its moisture is abstracted. However, the human organism possesses the capability of so damaging the wax envelope that this method can no longer serve as a differential method. Under such circumstances he uses his second method—the picrin method. This is carried out, as before, by staining in carbol fuchsin, then treating in picric acid-alcohol after pouring off the fuchsin for two or three seconds; then adding 3 or 4 drops of 15 per cent. sulphuric acid and more picrin until the film appears faintly yellow (this takes from five to ten seconds); then washing in water, and, lastly, drying. The picrin solution is made up by mixing equal parts of a saturated solution of picric acid and absolute alcohol. The bacilli, when stained in this way, appear brilliantly red, as do also the "*splinters*," and both are well contrasted against the yellow background. The method presupposes a trace at least of the wax envelope. One meets with one difficulty in carrying out this method. This is that it is extremely difficult to focus with high powers. He finds it best to first seek the yellow islands in which the red bacilli must be sought, under comparatively low powers, and then to apply the oil-immersion lens without moving the specimen. He claims that the picrin method is specific for acid-fast bacilli. Further, he believes that the evidence of damaged wax envelopes is of prognostic importance. When this is marked it indicates that the patient is getting the upper hand over his bacilli. The last method is called the "*colour-true method*" (*Farbaecht-methode*). This means that when the bacillus has once taken up carbol fuchsin it is unaffected by any other stain. All the bacteria which belong to the acid-fast group are colour true. No acid decolorizing is used. While tubercle bacilli from the human origin are probably better stained after Ziehl's method, other acid-fast bacilli show up much better as colour-true pictures. All three methods are therefore capable of distinguishing bovine from human tubercle bacilli under various conditions. He adds a few other remarks on the details and interpretation of the methods.

36. A Case of Cyclops.

MIZUO (XXXV *Versammlung, d'Ophth. Gesellschaft.*, Heidelberg, August, 1908) described a case of complete cyclops. The anterior brain looked like a placenta, the middle brain was maldeveloped; there was one central eye and one optic nerve. The rest of the body was normal.

CORRECTIONS.

IN the EPITOME of December 19th, 1908, No. 561, col. 2, line 25, the word "*sanatol*" was printed instead of "*sanatol*." In line 30 mention is made of viocol, which is described as the active principle of cod-liver oil; this should of course read "*castor oil*." We regret that these errors should have crept in through inadvertence. cc.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

37. Congenital Pyloric Spasm.

KOPLIK (*Amer. Journ. of Med. Sciences*, July, 1908) records several cases of congenital pyloric spasm and congenital hypertrophic stenosis of the pylorus in infancy, and in order to more clearly differentiate the varying forms which may be found he considers the subject under two headings. Notes of three cases are given typical of those in which there is a definite spasm of the pylorus initiated by some error in feeding, thereby causing an increased peristalsis of the stomach which eventually results in such pyloric spasm. The peristalsis may not be sufficiently marked to be visible, but the children vomit after every nursing, at times rejecting more than has been taken, a residual amount of food being retained by the stomach. The prognosis is good and operation is not indicated. Six cases are reported presenting initial symptoms as severe as the above but in which either a rapid improvement followed under observation, or after passing through many dietetic vicissitudes they recovered spontaneously on foods apparently scientifically most unsuitable. In the second class of cases, not only does pyloric spasm exist with peristalsis of the stomach, but in addition there is a distinct hypertrophy of the pylorus and a narrowing of the lumen from a distinct growth of new tissues, which can be palpably demonstrated as a hard nodular mass, and the peristalsis too is markedly visible. This latter condition presents all the symptoms of simple spasm in an aggravated degree, and in addition there is marked visible peristalsis towards the pylorus and constipation is more marked, the stools showing little or no milk faeces, but only bile-stained mucus. As regards prognosis the cases of simple spasm will generally be relieved by persistent trial of feeding, while many of the hypertrophic cases will eventually recover upon the same lines, only the rare cases requiring operation. Breast feeding is the ideal and should be given at long intervals and short nursings, and in artificial feeding small amounts at each feed should be given. Stomach washing appears to be useless and in some cases harmful, but enemata in the form of enteroclysis of small amounts of normal saline solution given several times daily are useful in maintaining nutrition.

38. X-Ray Diagnosis of Tracheo-Bronchial Adenitis.

LAUREATI (*Gazz. degli Osped.*, October 25th, 1908), continuing his researches in the diagnosis of enlarged bronchial glands, gives the result of a number of x-ray examinations of the thorax in 30 cases of children who were reasonably suspected (and in many cases proved) to have enlarged tracheo-bronchial glands. The net result was to show that such examinations possessed only a relative value in conjunction with other symptoms. Out of the 30 cases, no shadow at all was given in 19 cases, in 1 the shadow was seen anteriorly, in 5 posteriorly, and in 5 both anteriorly and posteriorly. The author suggests that further experience of the real or comparative value of x-rays in diagnosis might be gained by examinations in the post-mortem room. The results of experience so far seem to show that the chief value consists in affording confirmatory evidence, and for this purpose it seems to have about as much and as little value as the venous hum described by Einsteine Smith, and fully discussed by Laureati in a previous communication.

39. A Young Girl with a Deep Bass Voice.

SCHIEER (*Medic. Klinik*, October 25th, 1908) records the case of a girl of 16 with a man's deep voice. The mother died of phthisis. The girl menstruated fairly regularly for a year, when, at the age of 15, the menses suddenly ceased, and her voice changed from a beautiful soprano to a true deep bass. She now has a range of nearly four octaves, sings the deepest bass notes with ease, and also produces the most ideal falsetto tones. The speaking voice has remained a deep bass up to the present. Laryngoscopically the vocal cords are seen to be much broader and longer than in other girls; they are reddened, and during ordinary phonation leave a triangular space between them at the back. They only close completely when she phonates quite high. Externally the larynx appears larger than usual, with a very prominent thyroid angle. Schieer thought first the patient was a hermaphrodite, but the genitals proved entirely feminine, the

breasts well developed, the type of respiration entirely costal, and the disposition wholly that of a female. Examination with the x rays revealed no ossification of the thyroid cartilage beyond the slightest trace, just starting, in the posterior part of the laminae. The author asks if this is a case of abnormality—the sudden change of a woman's voice into a man's—and will the voice always retain its mannish character, or is it a case of perverse cracking of the voice at puberty? The removal of the testes in boys has a considerable influence on the growth and form of the larynx and on the voice, and, following changes in the female genital organs, the larynx has been observed to approach the male type. When the appearances accompanying the change of voice—that is, the redness and swelling of the cords—have disappeared, an attempt will be made to act on the larynx through the induction of menstruation. Special electrical treatment and systematic voice exercise will be undertaken.

SURGERY.

40. The Operative Treatment of Facial Neuralgia.

MORESTIN (*Bull. et Mém. de la Soc. de Chir. de Paris*, No. 32, 1908) publishes two cases of very severe facial neuralgia, in which complete and welcome, though it is anticipated only temporary, relief was afforded by operative treatment. In each of these cases the patient was a male. The first patient, who suffered "terribly" from facial neuralgia involving the regions supplied by the superior and inferior maxillary nerves on the right side, was, after failure of injections of alcohol and an attempt to expose and divide the roots of the affected nerves, subjected to a combined operation in which the author through a single long incision made in front of the sternomastoid muscle, ligatured the external carotid, extirpated the superior cervical ganglion, and finally, after division of the inferior dental near the process of Spix, tore away the upper portion of this nerve. This operation was followed at once by complete cessation of pain, not only in the region of the inferior dental, but also over the whole range of the distribution of the trifacial nerve. The interval between the date of the operation, which was performed early in October, and the communication of the report on November 4th is far too brief to present any definite conclusions on the value of the treatment applied to this case, but the author is disposed to think that by the combination of three different procedures, each of which is capable of affording for a time complete relief from pain, the chances of obtaining a durable result may be increased. The long delay in the relief of the neuralgia that usually occurs after sympathectomy alone was abolished in this case, the author holds, by the association of this operation with ligature of the external carotid. The vaso-dilatation due to the resection of the nerve is neutralized by the ischaemia resulting from the arterial occlusion, and thus, it is pointed out, the patient is guarded against painful consecutive reaction. The history of the second case is a record of a long succession of severe operations, including sympathectomy, practised from time to time in the course of the last years, with the invariable result, after intervals more or less brief, of recurrence of very intense neuralgic suffering. After an unsuccessful attempt made in October to expose the Gasserian ganglion the author trephined over the Rolandic region on the opposite side of the head. This operation, proposed and practised in a single case by Jaboulay, was, in Morestin's case, followed, after an interval of a few hours, by complete relief from much suffering. In both cases in which this operation has been practised for facial neuralgia the results have undoubtedly been very good. It is difficult, however, to explain these, and the period of relief in each case has hitherto been too short to allow of any sanguine expectations of an absolute and abiding cure. It is a remarkable fact, the author states, that though in his case trephining on the opposite side gave almost immediate relief, the large opening made in the cranial vault at the previous attempt to reach the Gasserian ganglion had not influenced in any degree the intensity of the pains. In the discussion of Morestin's report Schilean stated that a long experience of surgical interventions in cases of facial neuralgia had abolished all previous illusions as to the utility of such treatment, and that he thought of refraining from future operations for this affection.

41. Local Anaesthesia in Adenoid Operations.

F. HUTTER (*Wien. med. Woch.*, October 10th, 1908) has devised a method of anaesthetizing the pharyngeal tonsil by infiltration. Painting the tonsil must be repeated so often before the deeper parts become anaesthetic that the process is more objectionable than an operation without anaesthesia. If the curved needle of a syringe is passed behind the soft palate from the mouth it may enter the adenoid tissue, but probably does not pass sufficiently high to anaesthetize the roof of the naso-pharynx. Further, owing to the vertical direction of the needle track and the numerous clefts in the pharyngeal tonsil, a considerable quantity of any liquid so injected escapes downwards. In the writer's method the needle is passed through the nostril. A camel's-hair brush is soaked in a 10 to 20 per cent. solution of cocaine, passed through one nostril, slightly upwards towards the upper border of the posterior nares, and left there for a few minutes. The process is repeated on the other side. The deeper parts are caused to shrink, so that the upper border of the posterior nares and the adenoid tissue behind become visible by anterior rhinoscopy. The camel's-hair brush is then gently rubbed over these parts until they are superficially completely anaesthetic. If this part of the process is not carefully done the subsequent prick of the needle will be felt, and the patient, especially if a child, probably becomes unmanageable. The most satisfactory drug, for purposes of injection, is β -eucaine in a warm 5 per cent. solution with 0.8 per cent. of NaCl. Cocaine is unsuitable, as more concentrated solutions are required than are necessary for ordinary infiltration anaesthesia. Novocain is unreliable. The eucaine solution can be sterilized by boiling, is but slightly toxic, and is not followed, as are the vaso-constrictors, by secondary vascular paresis and haemorrhage. Its action is increased by the addition of 5 drops of adrenalin to each syringeful. The capacity of the syringe employed by the writer is slightly more than 2 c.cm (about 34 minims). The needle, which is straight and 12 cm. in length (nearly 5 in.), has a bayonet attachment to the syringe, from which it comes off almost at a right angle. The orifice at the point faces upwards. The needle is passed into one nostril backwards and slightly upwards towards the upper margin of the orifice of the posterior naris, where it impinges on the mucous membrane of the anterior part of the roof of the pharynx and the insertion of the pharyngeal tonsil a short distance external to the septum. This should be done under the guidance of the eye. Even if the dividing line between the posterior naris and the adenoid tissue is not distinct, there is, with practice, no difficulty in selecting a suitable place for insertion of the needle, which is passed on until it meets with the resistance of the basilar process, when its point is slightly elevated so as to reach the highest layer of the adenoid tissue. Considerable pressure is requisite to force the fluid into the tissues, and an easy flow indicates that the needle has not travelled sufficiently upwards to the pharyngeal roof. The process is repeated through the opposite nostril, half a syringeful being injected on either side. After waiting a short time the adenoids can then be removed, in the great majority of cases entirely painlessly. The method is especially applicable to older children and adults, though, in the writer's hands, it has often succeeded in children under 10, and not infrequently in those as young as 4 or 5. There should be no crying or struggling, and the growths can be removed as thoroughly as under a general anaesthetic with avoidance of the dangers inseparable from the latter. It is important not to frighten children by digital examinations or attempts at posterior rhinoscopy, which frequently render them unmanageable. Anterior rhinoscopy is usually sufficient for diagnosis.

42. Hydatid Cyst of the Stomach.

HARTMANN (*Rev. de Gynéc. et de Chirur. Abt.*, July-August, 1908) reported before a medical society on a specimen of hydatid cyst of the parietes of the stomach removed by Dujarier. A woman aged 65 was admitted into hospital for pains in the left flank. She had never suffered from any symptoms of indigestion. On palpation a rounded tumour could be defined in the left flank. It was of the size of a fist, firm, very movable, and not very tender. On account of these characters it was taken for a movable kidney. A lumbar incision was made with a view to nephrorrhaphy. The kidney was found to be in its normal place and perfectly healthy. The posterior layer of peritoneum was laid open, and then it was found that the tumour was situated in the stomach. The lumbar wound being closed, Dujarier opened the abdominal cavity anteriorly. The cyst was enucleated from between the mus-

cular and mucous coat of the anterior wall of the stomach. The patient recovered without any complications. Hartmann maintained that the case was unique. Tuffier, in discussing it, stated that he had operated on a case of hydatid cyst of the lesser omentum, which being closely applied to the lesser curvature felt like a tumour of the stomach, and was diagnosed as cancer of that organ.

OBSTETRICS.

43. Central Rupture of Perineum.

REISCH (*Monats. f. Geb. u. Gynäk.*, September, 1908) recently reported before a medical society a case of breech presentation, where the after-coming foot tore through the recto-vaginal septum and projected out of the anal ring. The perineum remained intact, but it had to be laid open from the vagina before the foot could be set free. More recently he attended a primipara, aged 21, where the second stage was lingering; at each pain the head passed the perineum, so that the vulval ring was pushed forwards. The midwife protected the perineum according to the usual practice, and at length the head was delivered. The perineum seemed intact, but on closer inspection an oblique laceration was detected in front of the rectum, and the shoulder could be seen pressing it open. Reich managed to make the shoulder pass through the uninjured vulval ring, and delivered the child, a well-developed female, over 7½ lb. in weight. Then it was clear that a central rupture of the perineum existed, over 2½ in. in length, and running from near the anus on the right obliquely forwards to the left, ending about the middle line of the perineum. The sphincter ani lay bare, yet unruptured, in the wound. The vagina, on the other hand, was severely lacerated, its posterior wall being torn away from the perineum, which formed a bridge over the torn tissues. The vaginal laceration reached to the rectum posteriorly, as far as the labia minora laterally, and passed upwards on each side of the posterior vaginal column, 2 in. on the left and a little over 1 in. on the right. There were some short fissures in the vaginal wall anteriorly, near the meatus urinarius. The bridge of unlacerated perineal tissue anteriorly had to be laid open in order to repair the damage to the vagina and deeper parts satisfactorily. The wound healed by second intention, as there had been much bruising of the tissues, but it ultimately healed very well. Reich discussed the mechanism of central rupture of the perineum and of rupture of the recto vaginal septum in labour.

44. Decapsulation of the Kidney for Eclampsia.

IN 1903 Sippel suggested, on the basis of conditions found in an autopsy, that eclampsia might be due to the displacement of a ureter causing a marked venous stasis of the kidney. The displacement of the ureter would be caused by the uterus increasing in size, and even when the cause of the displacement no longer acted, the hyperaemia would continue in the kidney. He therefore proposed stripping the capsule off the kidney in cases of venous hyperaemia or anuria. In discussing the value of this method of treatment for eclampsia, Ernst Runge (*Berl. klin. Woch.*, November 16th, 1908) follows out the history of the development of the suggested treatment. Edebohl independently came to a similar conclusion, and was the first to carry the idea into practice. He dealt with three cases. He had obtained an immediate increase in the quantity of urine secreted in 100 cases of chronic nephritis by decapsulation, at times obtaining enormous quantities of urine. In two of his eclampsia cases the emptying of the uterus did not have the desired effect, while the fits ceased after the decapsulation. Polano first carried out this in Germany. The fits set in after delivery, and ten days post partum he carried out the operation. The patient died, but he was of opinion that the procedure had exerted a beneficial influence on the diuresis and on the general condition. Gauss reported on a successful case. Asch, Wiener, Kleimertz, Frank, and Falgowski also were able to record successful cases. Others, however, did not have so much good fortune, and Esser-Müller, Haim, and Kleimertz lost patients after the operation. Bunni, too, attempted this method in three cases, but failed to prevent a fatal termination. The opinions as to which time is the best to operate are still divided. Some wish to operate after delivery has proved unsuccessful, while others consider that it should be performed as soon as the diagnosis is made. Bunni considers that decapsulation should only be attempted during the puerperium, when the fits continue, or when anuria is complete. He prefers to reserve the operation to those cases which offer no chance of recovery when treated by any other method. The observations on

the kidneys at the operation differ widely. At times the kidneys were tense, and protruded as soon as the capsule was divided; while other kidneys were soft, not enlarged, and soddish. In surveying the position Runge finds that of the 17 patients who had been subjected to the operation, 9—that is, 53 per cent.—have died. It is probable, in his opinion, that some of the patients who recovered might have done so without operation. Improvement only set in in two cases a considerable time after the operation. In other cases, however, the immediate increase of the diuresis and diminution in the quantity of albumen kept pace with the decrease in the number of clamptic fits, and it is therefore possible that the operation saved the patients' lives. It is impossible at present to give a definitive verdict as to the value of this operation in the treatment of eclampsia, but up to the present the results are not very promising. In the hands of a skilled operator, however, decapsulation is not a severe operation, and can be performed in about twenty minutes. It may, therefore, be tried in desperate cases when all other means have failed.

GYNAECOLOGY.

45. Inoperable Uterine Cancer.

IN discussing the treatment of inoperable cancer of the uterus, H. Freund (*Deut. med. Woch.*, December 3rd, 1908) finds that some difficulty is experienced in defining inoperability. When the malignant growth has spread beyond the limits of the pelvic cellular tissue and has involved other organs, when perforation of the bladder or rectum has taken place, or when marked cachexia, with dropsy and other terminal symptoms have presented themselves, there is no doubt about the inoperability. In less advanced cases the determination depends on the skill in examining, the experience, and the technique of the gynaecologist. The best way out of the difficulty is to consider as operable only those cases in which all the macroscopical cancerous tissue can be removed. When the disease has not advanced as far as in the cases described above, and the strength of the patient still admits of operative interference, he considers it advisable to consider the question of operative treatment of "inoperable" cancer. The operation, then, must include the removal of the uterus, and as much as possible of the pelvic connective tissue and vagina. In spite of the theoretical opinion that incomplete operations should be carried out vaginally, he believes that this operation should be performed through the abdominal wall. If done vaginally, the vulsella usually tear through, the bladder cannot be detached, and the haemorrhage can only be controlled by means of tamponage or permanently applied pressure forceps. The results obtained in this way are usually not better than those obtained by means of the canterly or sharp spoon, which only occasionally are satisfactory. As a rule the beneficial effects of these palliative operations only last for a very short time. During the last two and a half years he has operated solely through the abdomen. The object of the operations is not so much the prolongation of life as the arresting the spreading of the growth and the checking of the bleeding and decomposition. The results which he has obtained were particularly satisfactory with regard to the checking of bleeding and discharge. He illustrates this and other points by means of clinical histories of cases. The following points are especially emphasized: (1) That there is a sufficient preparation. The patient is put under an anaesthetic (deep anaesthesia is not necessary), and exuberant parts of the growth are removed by the sharp spoon or canterly, and then dried and disinfected. The drying and disinfecting is achieved by means of tannin-salicylates and repeated application of 3 per cent. peroxide of hydrogen. (2) At times it is advisable to perform a sort of high amputation in cases of cervical cancer, and to disinfect and dry prior to the more radical measure. (3) In the operation itself it is necessary to work rapidly and to provide ample protection of peritoneum. The removal of the malignant tissue is best done by means of Cooper's scissors, which will not lead to wounding of neighbouring organs. Naturally portions will be left behind; but this is unavoidable in inoperable cancer. (4) It is necessary to cover the whole of the field of operation by means of peritoneum. If healthy peritoneum cannot be made to unite exactly so as to shut off the soiled and infected area, it is better to limit the operation to ligation of the arteries. Objection has been taken to this severe procedure on the ground that the operation is a big one, the risks are considerable, and the possibilities are small. Freund answers

that if only those patients whose disease has not advanced so far as to render death imminent are chosen for the operation, the operation, which can be completed in forty minutes, is well stood, and within a short time the general condition improves very materially. The freedom from haemorrhage and discharge acts beneficially on the mind as well as on the body. The use of lumbar analgesia for general anaesthesia has further assisted in rendering this operative interference justifiable. With regard to pain in inoperable cancer of the uterus, the author has made the experience that morphine, opium, and the usual narcotics not infrequently fail. He has given a single lumbar injection of stovaine, and while this only obtained complete freedom from pain for one day the pain was never so intense afterwards that it could not be banished with aspirin or morphine.

THERAPEUTICS.

46. Serum Treatment of Epidemic Meningitis.

FLEXNER and JOBLING (*Journ. of Exper. Med.*, September, 1908) have analysed 393 cases of epidemic meningitis which were treated with antineurotoxin serum. Out of these, 295, or 75 per cent., recovered. In children under 1 year of age the prognosis is usually considered to be hopeless, but out of the 22 cases analysed by the authors 11 recovered. Of the 11 cases which terminated fatally, 10 were already in the third week of the disease when the treatment was commenced, and some were in a later stage; 6 or more presented well-marked symptoms of hydrocephalus; and only 1 was in the first week of illness at the time of the first injection. Of the 11 cases which recovered, 1 infant was 4 weeks old when first injected, all but three were in the first week of the disease, and none showed symptoms of hydrocephalus when the injections were begun. Of the 19 children in the series between the ages of 1 and 2 years, 11 recovered and 8 died. Analysis of these shows that only 1 case injected in the first week of illness died, while 6 cases injected in the first week and 5 injected from the second to the fourth week recovered. In patients of all ages the importance of early inoculation is emphasized. The histories of 361 cases were sufficiently explicit to enable the authors to ascertain with fair accuracy the date at which the treatment was commenced. Injections were given during the first three days in 123 cases; only 16, or 16.5 per cent., of these died. The treatment was resorted to from the fourth to the seventh day in 126 cases; 30 of these, or 23.8 per cent., died. Out of 112 cases treated later than the seventh day, 39, or 35 per cent., died. The histories of 110 cases afforded evidence of the influence of the injected serum upon the diplococci: in 100 of them the diplococci disappeared and lost viability quickly; in 10 instances the elimination of the organisms was slow. In several cases which recovered the spinal exudate was purulent to begin with, but rapidly cleared under the influence of the injections. It was also found, in favourable cases going on to recovery, that, correlated with the disappearance of the diplococci and the clearing of the spinal exudate, there was a fall, often very rapid and even critical, in the number of leucocytes in the general blood stream. The general conclusion at which the authors arrive is as follows: "It is our belief that the analyses of histories of cases of epidemic meningitis which have been presented in this article furnish convincing proof that the antineurotoxin serum when used by the subdural method of injection, in suitable doses and at proper intervals, is capable of reducing the period of illness; of preventing, in large measure, the chronic lesions and types of the infection; of bringing about complete restoration to health in all but a very small number of the recovered, thus lessening the serious, deforming, and permanent consequences of meningitis; and of greatly diminishing the fatalities due to the disease."

47. Atoxyl as a Tonic.

SCHACHT (*Med. Klinik*, September 13th, 1908) has systematically employed atoxyl during five years with excellent results and no harmful secondary effects. He gives intramuscular injections usually into the gluteal region, not too near the ischium, using slight massage afterwards to distribute the drug. Intravenous injections he thinks unnecessary. Out of all his cases he has never once observed any harmful effect or local irritation, a course taking one month when the injections were given every second day. He usually gave atoxyl in single doses as follows: 0.02, 0.04, 0.05, 0.03, 0.10, 0.12, 0.15, 0.15, 0.15.

0.15, 0.12, 1.10, 0.08, 0.06, 0.04, 0.02 gram, altogether 1½ grams, a small amount compared with that recommended in recent works. Three to five times as much arsenic is thus carried into the blood stream as is introduced when Fowler's solution or Asiatic pills are employed, and Schacht believes that the above dose may be safely increased. For the use of injections he recommends small bulbs containing the solution, which can be safely sterilized without destruction of the atoxyl solution. A 10 per cent. solution must be frequently renewed, since part of the atoxyl easily crystallizes out, and in this way danger of decomposition is also lessened. Atoxyl proved successful in the following diseases, where formerly arsenic seemed indicated, that is, chlorosis or anaemia, primary following malaria, or associated with nervous diseases, Basedow's disease, tuberculosis, convalescence after infectious diseases, general conditions of weakness, malnutrition, etc. Increase in good health, weight, red corpuscles, and haemoglobin always occurred, atoxyl proving effective in cases where the other arsenic preparations were either not tolerated or without effect. Schacht attributes accidents and failure to the use of excessive doses employed in attempts to find in atoxyl a specific for sleeping sickness, syphilis, pellagra, carcinoma, etc.

49. Vaccination of Bovines against Tuberculosis.

CALMETTE and GUÉRIN (*Ann. de l'Inst. Pasteur*, September, 1908) have made a further study of immunization by the alimentary route against tuberculosis, and conclude that by the ingestion of virulent tubercle bacilli, or of bacilli modified by heat, a relative degree of immunity may be conferred on either young or adult bovines. When at a later period animals thus treated are tested by causing them to ingest a large dose of virulent bacilli invariably fatal for the controls, one finds that at the end of four to six months they remain unaffected; that they do not react to tuberculin; and that their mesenteric, mediastinal, bronchial and retropharyngeal glands no longer harbour tubercle bacilli, inoculation of such glandular material being harmless for guinea-pigs. But experiments continued for a sufficiently prolonged period do not justify the assertion that these animals are capable for a longer period than a year of resisting artificial infection by the digestive tract or natural infection by cohabitation. When, eight or twelve months after having resisted a large test dose administered by the alimentary tract, the vaccinated bovines receive an intravenous injection of virulent bacilli in sufficient dosage to kill the controls in four or five weeks, it is found that the vaccinated animals, after a short period of malaise, maintain for six or eight months every appearance of perfect health. Nevertheless, they retain in their bronchial and mediastinal glands virulent bacilli capable of producing tuberculosis in guinea-pigs. These bacilli give no clinical manifestation of their presence, not even when the tuberculin test is applied: but after a period of delay, lasting from about six to eight months, the immunity of the animal disappears, and the bacilli present are then capable of setting up tuberculous lesions. Thus, cultures of tubercle bacilli, when introduced by the digestive tract, are finally absorbed in the mesenteric glands when not present in sufficient numbers to provoke lesions, but when introduced intravenously the bacilli remain alive and virulent in the groups of lymphatic glands draining the thoracic organs. Animals which are tuberculous or have been sensitized to tuberculin by two or three large injections of this substance in the veins exhibit a very marked resistance to reinfection or to the severer forms of infection by natural or artificial means, even when the tests are applied by the intravenous method. This resistance, though less in degree, seems to be of the same nature as that conferred by various methods of vaccination, such as: (1) Intravenous inoculation of human or bovine bacilli (Behring, Koch, and Schütz); or of homogeneous bacilli (Arloing); (2) subcutaneous inoculation of similar bacilli (Lignières, Arloing); or (3) subcutaneous insertion of reed sacs treated with collodion and containing cultures of bovine or human viruses (Heymans). These methods of vaccination do not produce a true immunity, since the animals so treated, though failing to react to tuberculin, continue to harbour in their bodies living and virulent bacilli, which are capable, when the animal's resistance is on the wane, of producing in their host grave lesions.

49. Cocaine and Novocain.

VERDERAME (*Zeit. für Augenheilk.*, xviii, p. 191) has made experiments to test the relative deleterious action of

cocaine and novocain upon the tissues. He decides that novocain is more likely to cause corneal lesions and detachment of the epithelium. When injected under the conjunctiva, novocain causes degeneration of the cornea. It is less anaesthetic than cocaine, and has only one advantage, it does not dilate the pupil. Injections into the anterior chamber cause well-marked ureal irritation, associated with alterations in the corneal endothelium and parenchyma.

PATHOLOGY.

50.

Protozoa in Pathology.

FREDERICK G. NOXY (*Proceedings of the Pathological Society of Philadelphia*, 1907) surveys the progress which has taken place in pathology during the half century which has elapsed since the organization of the society, with especial reference to the rôle of protozoa in pathology. In 1857 Pasteur published his first study on the mysterious phenomenon of fermentation. He looked upon the motile organisms which he encountered as animals or infusoria. Before two decades had passed the botanist laid claim to all the bacteria, a claim undisputed until the recent development of interest in the spirochaetes. Pasteur's investigation of one of the first-known protozoal infections—namely, pébrine, or the silkworm disease—demonstrated the transmission of a protozoal infection. The author reviews in turn the chief circumstances of discovery and the means of study of amoebae, trypanosomata, spirochaetes, sporozoa. In regard to amoebae, which are not directly dependent upon the living host cell, pure culture is a useful and desirable, if not actually necessary, condition to a thorough investigation; and with the improvement of culture methods it cannot be too strongly urged that morphological studies be supplemented by cultivation tests. In regard to trypanosomata, after collecting the most important conclusions of all workers, the author asks the question whether *Tr. gambiense* may not have been originally a mere variety of *Tr. brucei* which has acquired its destructive properties by repeated and brief passages through man, effected by the tsetse flies. It is worth bearing in mind that the protozoa as well as the proto-phytes are easily influenced by environmental conditions even to the extent of giving rise to a number of distinct strains or varieties. The number of spirochaetes has steadily grown during the past few years, and it is hardly necessary to point out the importance of giving close attention to the presence of these organisms in view of the recognition of a spirochaete in the tumours of cancerous mice by Gayford and Calkins and the questions it raises of their relation to the pathological process with which they are associated. In cancer, small-pox, scarlet fever, measles, yellow fever, rabies, and Rocky Mountain fever, protozoa have been credited with being the causative agents. The evidence, however, at present is either morphological or wholly speculative, and as such is open to doubt. It is only by exhaustive experimental tests and by the successful search for new methods that we may hope to gain the desired positive knowledge. Morphology alone seems powerless, and it must be supplemented by studies bearing on the physical, chemical and biological properties unless the crucial test—that of artificial cultivation—is first realized. In regard to modes of transmission, according to Stiles there are two general rules with reference to parasites and disease. Diseases which are accidentally spread by insects are caused by parasitic plants, particularly by bacteria, and those diseases which are dependent on insects or other arthropods for their dissemination and transmission are caused by parasitic animals, particularly by sporozoa and worms. To the first rule certain exceptions are known, but the second has been regarded as yet without exception, and the classification of certain organisms, as protozoa, is dependent upon it. The author brings forward considerations based upon analogy to show that the function of insects as active carriers of bacteria is a possibility which must be borne in mind. Hence the transmission of certain spirochaetal diseases by ticks does not afford a serious argument against the bacterial nature of the spirochaetes, and similarly, the part played by *Stegomyia* in the transmission of yellow fever does not necessarily imply a protozoal organism. In fact the evidence is strikingly suggestive of a spirochaete cause. An experimental solution of this question is desirable, and perhaps can be effected by injecting dialyzed and unaltered salt suspensions of the infected mosquito before the supposed life-cycle of the protozoan has been completed.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

51. Duodenal Diabetes Mellitus.

A. HERLITZKA (*Giorn. d. R. Accad. di Med.*, Turin, 1908, lxxi, p. 57), after discussing the diabetes described by Pfliiger in 1907 as due to removal of the duodenum or to separation of the duodenum from the pancreas in the frog, describes his own experiments. In these he attempted to paralyse the sympathetic nerve cells in the frog's duodenum by the injection of vaseline to see whether the frog would then develop glycosuria. Accordingly he injected pure vaseline into the duodenums of a number of frogs; some developed a slight transient glycosuria. Into other frogs he similarly injected vaseline containing up to 2 per cent. of nicotine; they all developed in one to three days marked glycosuria, lasting a week or until death. With yet other frogs he injected the nicotinized vaseline into the dorsal lymph sac; a few of these developed transient glycosuria after one to six days. Herlitzka concludes that duodenal diabetes is due to interference with the action of ganglia situated in the wall of the duodenum, and controlling reflexly the internal secretion of the pancreas: he adds that these ganglia are no doubt part of the sympathetic nervous system. In 1907 Pfliiger noted that removal of the pancreas in the frog, or even laceration of the mesentery between the pancreas and duodenum without any injury to the pancreas, gave rise to true glycosuria. A. Visentini (*Il Morgagni*, Milan, 1908, l, p. 479) discusses this duodenal diabetes, quoting from the literature; several German experimenters have failed to produce glycosuria in dogs by extirpation of the duodenum, or at most have found a transient glycosuria after this severe operation. Visentini removed the duodenum in three dogs, leaving the pancreas intact, and forming an external biliary fistula: death followed on the third, fourth, and twentieth days respectively, but no glycosuria was observed. In five other dogs he removed the duodenum and with it the greater part of the pancreas, leaving behind only the tail of the pancreas near the spleen. Death followed in two to eleven days, but no glycosuria occurred in any case. In the first three cases a trace of duodenal tissue—that around the ampulla of Vater—was left behind, but can hardly have been enough to protect the animals from duodenal glycosuria, if such a condition exists. Minkowski (1908) removed (from dogs?) first the greater part of the pancreas, and at a second operation the duodenum; no diabetes was produced. But when, at a third operation, the remaining fragment of pancreas was taken away, severe glycosuria at once followed. Visentini quotes the experiments of Gaultier (1908), who found that cauterizing the duodenal mucosa with silver nitrate produced severe glycosuria, lasting till death in four and eleven days in two dogs; Eichler and Silbergleit (1908), on the other hand, only obtained a transient glycosuria, the duodenal mucosa having been cauterized with caustic soda or with Paquelin's cautery.

52. Percutaneous Tuberculin Reaction.

E. MORO (*Muench. med. Woch.*, September 29th, 1908) has made some observations with regard to the percutaneous tuberculin reaction, which appear to him to be of importance. First, he records that when tuberculin has been rubbed into the skin at suitable situations, the reaction has occurred not only in the site of the application, but also in a situation placed in the site of the application. Next, he reports that the reaction occasionally appears disseminated at some distances from the site of application. In one case he observed a unilateral girdle form of reaction following the local reaction. In this case the tuberculin ointment was rubbed into the skin of the abdomen. From these three types of reaction he deduces that the direct toxic action of the tuberculin cannot have produced the changes, but that it may be accepted that the appearances depended on some effect acting on the central nervous system. He further noticed that when pure lanolin is rubbed in the skin no reaction is produced, but when tuberculin lanolin is rubbed in one place and pure lanolin is rubbed into another in the same patient a reaction was noticed in the site of the latter. This lanolin reaction was usually less severe than the tuberculin reaction, and was sometimes later in appearing, but was typical. Further, he was able to watch the entire disappearance of lichen scrofulosorum after local treatment with tuberculin ointment. He states

that this disappearance was incomprehensible until he learnt that the central nervous system took an active part in the production of the tuberculin reactions. He therefore believes that the percutaneous tuberculin reaction is chiefly a vasomotor phenomenon, or, as he defines it later on, an angioneurotic inflammatory phenomenon. Having come to this conclusion, he proceeds to argue that the same must apply to the conjunctival and to the cutaneous reactions to tuberculin, and also to the subcutaneous reactions. In raising the question whether the reactions are due to the intervention of an antibody, he states that if an antibody is to be excluded a specific peculiar irritability of the nervous system in tuberculous subjects must be assumed. This he describes as a specific nervous "allergy." He leaves it undecided whether this nervous allergy or the tuberculin antibody is to be accepted. He appears, however, to lean more in favour of the purely nervous theory. On the other hand, he cites a number of phenomena which would speak rather for the second solution. These include the absence of the reaction in the last stage of tuberculosis, the absence immediately after the appearance of the measles rash, the absence of the reaction after prolonged treatment with tuberculin, the exacerbation of old reaction foci on repeated tuberculin applications, Koch's focal reaction, the accelerated reaction in connexion with a repetition of the test, the so-called secondary tuberculin reaction, and the long incubation period of the apparent inflammatory phenomenon.

53. Bilateral Pleural Effusion after Radical Cure of Hernia.

MAUCLAIRE has recently insisted upon the liability of a radical cure of inguinal hernia to be followed by pulmonary embolism. Mollard (*Lyon Med.*, November 29th, 1908) records a case in which the infarct was accompanied by bilateral effusion as well as by haemoptysis, a combination of signs which at first caused a suspicion of tuberculosis. His patient, a man aged 20, with a good personal and family history, was operated upon for left inguinal hernia on January 17th. The operation was very simple, and the cicatrix formed normally without inflammation, and with no visible sign of phlebitis about the leg or abdominal wall. The temperature rose on January 20th, and remained above normal until the 24th, when sputum stained with blood was first seen. The slight haemoptysis continued, and the temperature, after being normal for a week, rose again. On February 3rd signs of pleural effusion were found on both sides, more particularly on the right, from which some rose-coloured serum was obtained. This on examination was found to contain many red blood corpuscles, endothelial cells, and haemocytes (polynuclear 79 per cent., lymphocytes and other mononuclear 21 per cent.). On February 15th all signs of effusion had disappeared, and the patient seemed perfectly well. There was throughout a striking contrast between the gravity of the chest symptoms and the insignificant disturbance of general health. The absence of tubercle bacilli in the sputum, the rapidly favourable evolution of the affection, and, later, the negative result of inoculation, were considered sufficient for a diagnosis of post-operative infarct. It is probable that such embolism is due to a phlebitis not sufficient to block the vein or to interfere with healing of the wound by first intention. According to Nélaton, such an occurrence is frequent after operations in general, and explains slight pyrexial and pleuritic pains which have hitherto been attributed to chill.

SURGERY.

54. The Treatment of Undescended Testis with Inguinal Hernia.

COLEY, of New York (*Annals of Surgery*, September, 1908), discusses the treatment of abnormalities in the transit of the testis which are associated with inguinal hernia, and publishes in support of his views on this subject an analysis of 126 cases of such mixed defects on which he has personally operated. This surgeon states that there is by no means uniformity of opinion as to the indications for surgical intervention in such cases, and that also a wide difference exists as to the best methods of operation. Furthermore, but little information has hitherto been

afforded concerning the results of operative treatment. His own observations, as well as a careful study of the reports of other surgeons, have led Dr. Coley to certain definite and important conclusions. The undescended testis, he holds, is almost invariably of little or no functional value. It often gives rise to considerable pain, and is more subject to inflammatory attacks than the normally descended organ. Possibly, though this is by no means proven, it is more subject to malignant disease. The undescended testis should never be sacrificed, the author holds, in children, and very rarely in adults, as it has been proved that it is possible to effect a radical cure of the hernia without the removal of the organ. In childhood the testis, even if it never attains any functional value, is nevertheless of use in developing the male characteristics of the child as well as in promoting its general health. In the adult it should be retained for its influence upon the mentality of the subject, if for no other reason. An operation should seldom be performed under the age of 8 years, unless the accompanying hernia demands surgical intervention. Those who advise such treatment on very young children ignore the fact that in a large proportion of cases of undescended testis in such subjects the organ will reach the scrotum by the age of puberty without surgical interference. An exception to this rule, however, occurs when the defect is bilateral. Abdominal ectopia, unless bilateral, had better be left untreated, as operative intervention in such cases is difficult and by no means free from risk. The main principles of any operation likely to do good must be free opening of the inguinal canal by Bassini's incision; thorough freeing of the testis from any adhesions or peritoneal bands, even with the sacrifice of some of the veins if necessary; depression of the testis into the scrotum; suturing of the canal without transplantation of the cord. The present tendency in favour of giving up all forms of suturing the testis, either to the scrotum, the other testis, or the thigh, is, the author believes, fully justified. As satisfactory results may be obtained without cutting away all the structures of the cord except the vas and its vessels, this radical step, it is held, is very seldom indicated. In the same number of the *Annals of Surgery* Dr. Starr of Toronto describes a new operation for undescended testis which he has practised, he states, with very excellent results, and which he thinks can be applied with good prospects of success in cases of retention of the testis in the inguinal canal just within or outside the external ring. In this operation the testis after the coverings of the cord have been dissected away, is sutured to the lower end of a pouch made by finger pressure and blunt dissection in the scrotum, and is there secured by a loop of silver wire, which serves as a splint to retain it in its depressed position.

55. The Influence of Trephining on Optic Neuritis.

VON HIPPEL (*XXXV Versamm., d. ophth. Gesellsch.*, Heidelberg, August, 1908) draws the following conclusions from the study of 221 cases where optic neuritis was present and the skull was trephined. In the majority of cases the neuritis improved for a long time, and sometimes permanently. Improvement in vision is marked if the operation be performed early, but when the remaining vision is very small there is no such improvement. In most of the cases under examination the operation was delayed too long. In those cases where vision is improved life is also prolonged, and so the operation is advisable from this point of view. Trephining may result in complete cure, for in many cases which have all the clinical aspects of cerebral tumour there is really only a 'false tumour,' a chronic hydrocephalus, an acute hydrocephalus, or a serous meningitis. If these cases be not operated upon the result is sometimes good, but they often die. The risks of the operation are by no means negligible, but when it is undertaken solely to improve sight the danger is much less than in trephining for other reasons. The total mortality of all cases combined is, according to von Bergmann, no less than 47.7 per cent. The death-rate can be diminished by taking certain precautions, such as anaesthetizing with chloroform and not with ether, the two-stage operation, coicizing of the dura, slow escape of the cerebro-spinal fluid, immediate suture of the wound, and simple trephining, instead of osteoplastic methods. It is not always necessary to open the dura to reduce the intracerebral pressure. Cerebral hernia is necessary if we are to obtain the desired result, but we must keep it within reasonable dimensions. If the tumour can be localized we should trephine over it, otherwise it is best to select the right temporal region. In spite of possible bad results, it is always correct to trephine as soon as sight begins to fail.

OBSTETRICS.

56. Puerperal Fever and its Treatment.

MAX HENKEL (*Deut. med. Woch.*, Nos. 43, 44, and 45, 1908) shows that sepsis and pyaemia in the puerperium are caused by various types of streptococci, some of which he believes are introduced from without and others are already in the vagina. It is, in his opinion, impossible at present to determine which forms present the greatest dangers to women, and all he is inclined to say is that the Krönig-Menge streptococci are non-pathogenic. Even the appearance of haemolysis does not necessarily carry with it the most marked virulence, although he believes that the prognosis of an infection with streptococci, in which the cocci are found in numbers in the blood and present Schottmüller's phenomenon, is extremely serious. The author discusses at some length the bacteriology of puerperal fevers, and then passes on to speak of the prognosis. In the first place, he finds that the diminution of the neutrophile leucocytes and the loss of red cells, which Kownatzky regarded as a bad sign, cannot be definitely relied on, and offers very little practical value. The behaviour of the pulse and temperature are important prognostic signs when taken in conjunction with the general condition and controlled frequently. The fact that recent haemorrhage, as well as other occurrences, may influence both must render a mere objective determination of the pulse and temperature valueless. The possible source of infection can often be determined, and when scratches and other traumatic lesions can be discovered it will be found that the more extensive these are the greater is the danger of infection. He deals with the methods of conducting the labour as being of importance for the prognosis of an infection, and also concerns himself with the influence of decomposition of the liquor amnii on the prognosis. The way the uterus undergoes inversion and the presence of blood clots are also points which should be regarded. These and many other details are considered as influencing the chances of infection during the puerperium, and Henkel hints from time to time at various preventive measures, although he attempts to limit his remarks to the actual infection, its prognosis, and its treatment. Passing on to the latter, he arrives at a conclusion, at the end of a somewhat lengthy argument, that puerperal sepsis finds its best treatment in the surgical removal of the uterus, and that puerperal pyaemia ought to be treated by ligature of the thrombosed veins. He holds that serumtherapy, up to the present, has been a failure; that collargol has scarcely a better record; that the results obtained from those drugs, like nucleogen, which induce a profuse leucocytosis, have not been of such a character as to induce the obstetrician to pin his faith to their action, and that other methods of treatment are too symptomatic to be considered as curative. He dwells on the indications for the extirpation of the uterus, which he considers should be performed vaginally, and for the ligature of the thrombosed veins. He insists on the proper time being chosen for these procedures, and feels justified in predicting far better results than have hitherto been achieved, if the indications are well defined and carefully adhered to.

GYNAECOLOGY.

57. The Menopause.

VINAY (quoted in the *Journ. de Méd. et de Chirurg.*, September 10th, 1908) first refers to the functions of the ovary—namely, the expulsion of the ovum, the destruction of toxins which are formed during the menstrual period, and the production of an internal secretion which neutralizes the vasomotor toxins and which has an influence both on the uterus and on the whole body. This secretion possesses several properties. It reduces in a very marked way the blood pressure, and, when absent, hypertension occurs; this takes place when the menopause sets in. Secondly, it influences general nutrition by stirring up internal combustion and by increasing oxidation. Thirdly, it acts on the bulbo-medullary nervous system, and, when absent, tachycardia and anginal attacks are prone to occur. Fourthly, the internal secretion possesses a destructive action on certain waste products of the organism and prevents toxæmia. Amongst the most serious manifestations arising from deficient ovarian function the author refers to are hypertension, followed by cardiac troubles and tachycardia. At first the symptoms are vague, the patients complaining of palpitation, which becomes more and more frequent; later, attacks of dyspnoea occur, or, in other cases, attacks of paroxysmal tachy-

cardia, followed by vasomotor troubles (skin pallor, cold extremities, anginal attacks). Oedema of the legs only occurs at a late stage, and is often accompanied by slight albuminuria which is of a transitory nature. Remissions of the symptoms occur from time to time, the attacks lasting from six to seven days. Although during these attacks a high blood pressure is the rule, in some cases the pressure is subnormal, and in such cases marked muscular weakness and moral depression are present: the cardiac action is weak, and these disturbances are liable to last for weeks or months at a time. Amongst less common manifestations of the menopause the author refers to symptoms connected with the bladder and kidneys. Lumbar pain, violent headache, vomiting, diminution of urine, and sometimes albuminuria, are not very uncommonly found to occur. In thin women with a prolapsed kidney the organ can be felt to become painful and swollen. It becomes less movable and a generalized oedema may occur, together with a marked diminution in the amount of urine. If chronic nephritis be present there may be a sudden increase in the symptoms of the disease at the onset of the menopause. Urinary lithiasis sometimes occurs and may cause marked pain, and the presence of vesical calculi may give rise to troublesome symptoms. Pain localized to the neck of the bladder is a troublesome and often very persistent symptom arising during the menopause. The pain begins at the commencement of micturition and diminishes as this act is accomplished. Haematuria has also been known to occur, often coinciding with attacks of uterine bleeding. As regards treatment of the symptoms, for the uterine bleedings injections of hot water are often efficacious, and when combined with warm baths the insomnia, vertigo, palpitation, etc., often yield readily. If haemostatic drugs are necessary ergot should be given either by the mouth or subcutaneously, and in severe cases of uterine haemorrhage a mixture of the fluid extracts of hydrastis, hamamelis, and viburnum may be employed. Solution of adrenalin may be used, but its marked vaso-constrictive effect is always followed by great vaso-dilatation. Other drugs which may be used are stypticin, hydrastis canadensis, and calcium chloride. For the congestive attacks purgatives are useful, especially the saline purgatives, which are of great value in patients who suffer from flushings of heat, tachycardia, vertigo, etc. For the nervous depression arsenic, iron, and the glycyero-phosphates are of value, either singly or combined. Sedatives and hypnotics, such as opium, chloral, bromides, and sulphonal, are better avoided. For the nervous excitement one may employ hot baths, valerian, belladonna, etc., and for the pains antipyrin.

58. Diagnosis of Uterine Retrodeviations.

LAPOINTE (*La Clinique*, May 29th, 1908) writes that retrodeviation means the displacement of the uterine fundus backwards, with displacement of the cervix forwards. He finds that retroflexion is always associated with retroversion. The retrodeviated uterus is either movable or fixed by adhesions; these are the result of lesions of the adnexa, which are a cause of retrodeviation. In most cases a displacement is tolerated for a time at least without giving rise to much discomfort; an accident, such as a fall or an effort, may call attention to the condition. Pain and menstrual disturbance are the usual symptoms; there is a feeling of weight and radiating lumbar pain. Menorrhagia is a common symptom, and may be sufficiently severe to cause anaemia. In young girls a profuse and painful flow is the only symptom. In women who have reached the age of the menopause, the abnormal position tends to prolong the menstrual period. Leucorrhoea may simulate a "false metritis"; difficulty of micturition and defaecation are unusual in these cases, but pressure of the cervix on the neck of the bladder is liable to provoke frequent and painful micturition. Constipation is a common symptom, and is often accompanied by headaches, indigestion, and neurasthenic symptoms. Pain and pelvic discomfort are aggravated by the presence of adhesions and the disease, possibly latent, which has produced them. A vaginal examination shows the cervix to be lying directly behind the symphysis and lower than is normal; the fornices are empty, and the fundus is detected in the hollow of the sacrum; it is then possible to determine whether the uterus is simply retroverted or whether it is acutely flexed. The mobility of the uterus depends upon the condition of the adnexa; when the latter are swollen, painful, and adherent the uterus is generally adherent, fixed, and irreducible. Efforts to reduce it may result in the rupture of a pyosalpinx. When there are no adhesions the uterus is replaceable by digital manipulations; the fundus is pressed up and forward by the fingers

inserted in the vagina, the hand on the abdomen exerting forward pressure on it while the fingers in the vagina assist by pressing the cervix backwards. Should the uterus be entrapped in Douglas's pouch this manipulatory effort is unsuccessful. The pressure should be slow and continued for some length of time; it is facilitated if the patient assumes the genu-pectoral position. The cervix may be seized and drawn down, with the result that the fundus also descends, and two fingers can then be passed into the posterior pouch to assist in replacing it. If neither method is successful the uterus is probably fixed by adhesions. In virgins it is better to insert the fingers into the rectum instead of the vagina. When the abdominal wall is very thick it is possible to mistake for a retroflexion a fibroma or adherent tube or a collection of blood or pus occupying the pouch of Douglas. A careful vaginal examination is required to determine the relation of the mass to the uterus. When the uterus is involved in a mass of inflammatory adnexal adhesions the prognosis must depend upon the character and extent of the pelvic mischief. A retrodeviation, however simple, does not recover spontaneously; it is generally increased by pelvic affections, menstrual disorders, and neurasthenia. The advent of the menopause aggravates the symptoms; it is only in senile involution that the misplacement ceases to exercise an unfavourable effect. These misplacements are one of the causes of sterility; conception often occurs promptly when the position has been corrected. The presence of inflammation and adhesions tends to prevent conception, and there is a liability to tubal pregnancy. When conception does occur in a retrodeviated uterus the patient is exposed to unusual risks, with an increase of functional trouble and *malaise*. In the fourth month it is not uncommon for the gravid uterus to reduce itself spontaneously; if this does not happen an abortion will generally result. The chief danger in these cases is from pressure on the bladder and urinary system, which has been known to produce a fatal rupture, or death from uraemia. A woman who shows the usual signs of pregnancy and who complains of bladder disturbance, should be carefully examined to decide the position of the uterus. The further pregnancy has advanced the more difficult it is to recognize the cervix pressed up behind the symphysis, while a large soft mass, the gravid uterus, fills the pelvis.

THERAPEUTICS.

59. The Treatment of Neuralgia by Alcohol Injections.

IN 1903 Schlösser described a new method of treating neuralgia by injections of alcohol. Since that time a few authors have written on this subject, but practically no new method or material modification of the original method has been suggested. W. Alexander (*Berl. klin. Woch.*, November 30th, 1908) states that he has adhered to Schlösser's technique. It was found that 70 to 80 per cent. alcohol damages a nerve with which it comes in contact. The idea of utilizing this action was first awakened in connexion with convulsive affections of motor nerves, such as the tic convulsif. Sensory nerves were also chosen for the action in painful conditions like neuralgia. The nerves were found after such treatment to be degenerate, and eventually to become absorbed. The symptomatic effect of the injections is to produce anaesthesia of sensory nerves or paresis and paralysis in motor nerves. It has further been found that the sensory nerve fibres are less resistant toward the effect of alcohol than are the motor fibres. Leaving the question of applying the idea for convulsive affections, he limits himself to the injections for neuralgias. Good results have been obtained by many operators in sciatica, but Fischler and Erb have seen in man, and Finkelnburg in animals, that the motor fibres are too markedly affected by the injections to warrant the procedure. The author produced a marked paralysis of several months' duration of the peronei. In this case he injected 1 c.cm. of a 75 per cent. alcohol into the sciatic nerve. He says that it may be possible to avoid such occurrences by employing weaker alcohol. In the treatment of pain in pure sensory nerves, such as the trigeminal, extraordinarily good results follow. He describes the technique somewhat as follows: The alcohol can be injected either peripherally or centrally—that is, in the case of the trigeminal nerve at the foramen rotundum or ovale. Since it is never certain whether the affected portion of the nerve is central or peripheral, the author first tries the effect of the former, and, when this fails, goes closer to the brain. It is still uncertain whether recurrences take place more frequently after the peripheral than after the central injections. If this proves to be so,

it will become necessary to inject centrally in every case. The injection syringe has a capacity of 2 c.cm., and a variety of different shaped needles are fitted. The walls of the needles are thickish, as it is important to have them as strong as possible to ensure against breaking. The point is rounded, so that vessels are not injured. The skin is anaesthetized by Schleich's infiltration, but no further anaesthesia is permissible, as it is often important to ascertain whether pain is being produced or not. For peripheral injection in trigeminal neuralgia the needle is introduced straight down to the bone in the direction of the supra-orbital, infra-orbital, or mental foramen, and an attempt is made to enter the canal for a short distance with the needle. This is not difficult in the infra-orbital canal. The patient usually calls out at this time. The pain should correspond to the pain felt in the neuralgic attacks. If the pain corresponds, the injection is immediately begun. No blood may be issuing from the cannula. The syringe is then applied and 0.1 c.cm. to 0.2 c.cm. is slowly injected. This produces acute pain of short duration. As soon as this is over the same quantity is again injected, and at each successive injection of the small quantity the pain which follows is less. After from 2 to 4 c.cm. has been injected the area is analgesic. Central injections are more difficult, but if the operator has taken the trouble to study the anatomy of the various nerves carefully and practised the injections on the dead body the difficulties are overcome. No one should attempt to inject centrally without such previous study. After a successful injection one or more attacks of pain not infrequently appear. However, within a short time no more pain sets in and the neuralgia becomes cured. Each branch must be injected separately until no further pain occurs. The author reports that even when the pain is due to organic disease of the brain it can be relieved in this way, and cites a case in support of this. In comparing this method with other forms of treatment he mentions resection of nerves, which has the disadvantage of requiring a general anaesthetic, and, further, of leaving an unsightly scar. Removal of the Gasserian ganglion is a dangerous operation, and is only performed for cases in which the pain is intolerable. He contends that where the removal of the ganglion can cure, alcoholic injections can also cure, and that the latter must be preferred. In some cases it is necessary to repeat the treatment for recurrences, but he quotes a case to show that the patient willingly submitted to the injection for the second time, and that it was permanently successful. The supposed dangers of the procedure are necrosis of the skin, paralysis of motor nerves, and injury to large vessels. He has not met with any of these ill-effects save the temporary inclusion of motor nerves. In conclusion, he deals with the indications for the injections, and particularly in the distinction between true neuralgia and hysterical or neurasthenic pain. It is easy to determine whether the pain has a true localized character and radiates in a characteristic manner. He pleads for a freer use of this method.

50. Arsacetin in Syphilis.

IN speaking favourably of a number of arsenic preparations in the treatment of syphilis, A. Neisser (*Deut. med. Woch.*, August 27th, 1908) lays emphasis on the fact that mercury is a true specific for this disease, and he does not suggest that mercury should be replaced by arsenic. Given in suitable doses, mercury can remove the symptoms, kill the virus, and therefore cure the patient of the disease without giving rise to toxic symptoms. He is, however, able to show that arsenic is also capable of curing syphilis. Atoxyl was first used in the treatment of syphilis by Uhlenhuth, Hoffmann, Roscher, and Salmon, after extensive animal experiment. The results obtained on man are, however, not of such a nature to admit of definite deductions being made until many years have passed. Uhlenhuth, the author, and Metchnikoff have shown in animals that arsenic can render the syphilitic poison in the animal body absolutely harmless without producing toxic effects. Some animals even react better to certain arsenic preparations than to mercury. Arsenious acid, even in large doses, proved itself incapable of achieving this end. Given by subcutaneous injection, it produced abscesses, infiltrations, and necrosis. Neisser is, however, prepared to believe that in combination with some other arsenic preparation, and given by the mouth, it may yet be found useful, as it has been in experimental trypanosomiasis. Coccyliates are not of use. In his experiments, atoxyl exhibited both preventive and curative actions. The former could be demonstrated by giving the material from five to seven days after infection, and in one case even thirteen days after. All the animals remained healthy when atoxyl was given in sufficient doses. No toxic effects manifested

themselves. Even the latent virus was killed with atoxyl in animals. Next the author reports on his experiments with a new atoxyl preparation which owes its existence to P. Ehrlich, and which is called arsacetin. The aim which Ehrlich had in view was to prepare an arsenic compound which should possess the same action as atoxyl without being so toxic. It is especially the danger of optic atrophy which has caused many clinicians to refuse to use atoxyl altogether. The danger of atoxyl, however, has been shown to be partly due to impurities, and the French authors insist that the German atoxyl was responsible for far more accidents than the French atoxyl, and that the latter was purer. Lately the German preparation has been altered, and it is to be hoped that blindness and other serious effects will not occur in the future. Arsacetin or sodium acetyl-(p)-amido-phenyl arsenate is stable even at high temperatures. It proved to be far less toxic than atoxyl when compared in consideration of the arsenic content; 5 grams of atoxyl is equal to 6 grams of arsacetin. In animal experiment Neisser found that arsacetin was at least as powerful a curative agent in syphilis as atoxyl. He therefore has employed it in a number of his syphilis patients, and believes that he can recommend its use. He is of opinion that the atoxyl preparations and mercury can be applied simultaneously with advantage. The certainty that mercury acts well renders it inadvisable to replace it by a new drug whose action is less well known. But as animal experiment has yielded such good results, he considers that use should be made of the new preparations. So far none of his patients have exhibited any undesired effects from arsacetin, save a slight disturbance of the stomach and intestine. The simultaneous drinking of an alkaline water or taking of burned magnesia appears to remove even this action. Patients suffering from parenchymatous affections of the organs should not be given arsacetin; those suffering from nephritis may be given it if care be exercised, but if the kidney symptoms are increased the drug should be stopped at once. He gives injections of 0.6 gram of arsacetin on two consecutive days each week. He is uncertain whether the results would be equally satisfactory if an injection were given every fourth day. He has given the injections for periods up to ten weeks, and the maximum total quantity given in one course of treatment was 14 grams. The substance is given in 10 or 15 per cent. solution, but if the latter is employed it must be warmed, as arsacetin precipitates in this strength in the cold. It can also be given internally. The substance can be obtained from the "Farbenfabrik" in Höchst a. Main (formerly Meister, Lucius, and Brünig).

PATHOLOGY.

61. Etiology of Chronic Nephritis.

HAVEN. EMERSON (*Archives of Internal Medicine*, June, 1908) undertook experiments upon dogs to effect changes in the blood supply of the kidneys. Various means were used, such as inhalation of alcohol, ether, chloroform, amyl nitrite; intranephritic injection of alcohol (25 per cent.), adrenalin chloride (1 in 1,000); intravenous injections of acetate of lead (10 per cent.), adrenalin chloride (0.1 per cent.), gelatine (5 per cent.). Only dogs secreting urine free from albumen were used, and this led to the rejection of eleven dogs in the choice of fourteen. Their diet was carefully regulated, and their requirements were regarded. Seeing that circulatory disturbance resulting in a stagnation of venous blood, or a diminution in the supply of arterial blood is an almost constant accompaniment of the accumulation of connective tissue it was sought to produce the change experimentally in the hope of arriving at some conclusions relative to the effect of the reagents used. The paper contains a complete and pertinent discussion on the etiology of chronic nephritis. The causes usually recognized come under the four headings: (1) Infectious diseases; (2) gout, rheumatism, syphilis, plumbism; (3) vices of appetite; (4) errors persistent or frequently repeated in the circulation—for example, cardiac disease, etc. The author concludes that chronic nephritis in man is due to conditions which have as a common factor a more or less severe and prolonged stagnation in renal blood supply, and although this factor is often accompanied by the presence of irritants which we recognize as injurious to the kidney substance, inefficient blood supply alone will cause, first an error in the function and later an alteration in the structure of the kidney. The fault in function will cause more or less disturbance in the body at large according to the degree of circulatory compensation which can be maintained.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

62. The Heart in Convalescence from Acute Infectious Disease.

BEVERLEY ROBINSON (*Amer. Journ. Med. Sci.*, December, 1908) considers the care of a patient during the early days of convalescence from an acute infectious disease, in view of its influence on the comfort and usefulness of his after-life, a matter of prime importance, and one which receives less than deserved attention in medical textbooks. And while the general nutrition and the muscular and nervous systems all require consideration at these times, it is the heart which most often and most urgently calls for careful watching and governing. Especially is this so in typhoid fever, diphtheria, influenza, pneumonia, and scarlet fever, and most of all, of course, in acute rheumatism; but this last, in consequence of the frequency with which it is associated with definite cardiac complications of the nature of endocarditis or pericarditis, forms a class of its own and does not come into the present consideration. The various toxins of these diseases, in cases of any severity and duration, produce certain definite pathological changes in the heart muscle and nerves which are more or less common to them all. The muscle bundles are separated by small lymphoid cells, the fibres are sometimes ruptured, the individual cells are swollen and show granular or fatty change, while the striæ are feebly marked and the nuclei have often disappeared. Later the heart muscle may become hyaline or even fibrous. These changes may be general throughout the heart or may occur in discrete patches. The cardiac nerves show fatty infiltration and cloudiness of the sheaths and irregularity of the axis cylinders. The heart as a whole is flaccid, thin-walled, and easily torn, and often contains soft or sometimes fibrinous thrombi, especially on the right side. Sometimes, however, in cases of death from heart-weakness following an acute infectious disease, no organic change in the muscle or nerves is discoverable, though evident cardiac dilatation is present *post mortem*, and in these cases the real cause of the weakness is not known. Such changes being found at autopsies in these diseases, the author concludes that they are present in less degree during life, and that they extend beyond the acute stage of the disease into the early days of convalescence. In view of this assumption, how is the early part of the convalescence to be managed? The results of the author's experience have led him to the following practice: In typhoid fever the patient does not sit up until the temperature has been normal for seven to ten days. A pulse increased in frequency, irregular, and occasionally intermittent indicates that the sitting up must be restricted and watched, while the addition of a soft systolic mitral murmur with accentuation of the pulmonary second sound, or of a weak and toneless first sound and a feeble, rapid, irregular, sometimes intermittent heart's action, means that the sitting up should be discontinued altogether. In the absence of any of these the patient leaves his bed after a few days, and a little later begins to walk about the room, and their appearance at any time shows that advance has been too rapid, and that retreat must be made until the point is reached at which they disappear again. Other indications of too rapid advance are a subnormal temperature with diminution in the specific gravity and amount of the urine and the presence of a little albumen. Much more urgent danger signals still, as indicating a liability to sudden heart failure, are marked slowing of the pulse and heart. When these are present, attacks of acute dilatation, evidenced by sudden faintness, pallor, and blueness, or perhaps by sudden death, and due to failure in some cases of the muscle and in some cases of the nerves of the heart, are to be feared. They are specially apt to occur in convalescence from diphtheria. The special danger to the heart in scarlet fever is from the complicating nephritis or rheumatism in the third or fourth weeks of the disease giving rise to dilatation or endocarditis respectively. In pneumonia clotting of the blood is another danger, and one which is more commonly found in this than in any other infectious disease. As to treatment, Robinson emphasizes the prime importance of rest, enough in degree and in duration after acute infectious diseases in order to prevent cardiac dilatation with its unfortunate consequences immediate and remote. Rest for the mind is of no less importance than rest for the body. Enough

rest, with maintenance of careful watch for any of the above-mentioned signs at each advance in the convalescence, is the one thing needful. Later in the convalescence, especially after typhoid fever and influenza, he has found the Nauheim treatment of great value. With regard to drugs, in the attacks of acute failure he finds strophanthus, followed at once by ammonia or alcohol, the most rapid and efficient heart stimulant. Adrenalin ($\frac{1}{10}$ grain) by mouth or hypodermically is of undoubted value. Strychnine and digitalis are of use sometimes. Clotting of blood in pneumonia may be guarded against by giving ammonium carbonate or citric acid, and after influenza quinine or, better, cinchona bark, has a special value as a general tonic and a protection against cardiac dilatation.

63. Radiculitis.

MIRAILLIÉ (*Journ. Méd. de Bruxelles*, September 10th, 1908) considers the subject of nerve-root inflammation under two main forms, according as the anterior or posterior roots are involved. When a motor root is involved the muscles which receive their innervation from this root become paretic or paralysed, and their muscular power progressively diminishes, the degree of the loss of motor power being proportional to the severity of the pathological process. The affected muscles atrophy and in severe lesions may completely disappear and antagonistic muscles bring about vicious attitudes which are permanent. Tendonous reflexes diminish and then disappear. Electrical examination of the affected muscles shows the classical signs of a lesion of the peripheral motor neuron. When the sensory roots are involved there occur feelings of painful swelling and heaviness, which become continuous more or less and interrupted from time to time by extremely violent paroxysms of pain—in Pott's disease they were described by Charcot as "pseudo-neuralgias"; in tabes they constitute the lightning pains. These pains are always very severe and definitely localized to certain regions, and from being at first paroxysmal they become gradually continuous. Déjerine has laid special importance on what is spoken of as "the sneezing sign," that is, a very acute pain occupying the whole extent of the region supplied by the affected root, and occurring when the patient sneezes. When the nerve root has become destroyed the pains diminish and may disappear, to be followed by alterations of sensibility, such as paraesthesia, and at the same time the "sneezing sign" disappears. On pressure the peripheral nerves are painful, but not so markedly as in peripheral neuritis. At the beginning of the trouble one finds on examination areas of hyperaesthesia, which later on become less sensitive than normal; the sensory disturbances show themselves in all the different forms of sensation—touch, pain, heat, and cold—and the deep, muscular and joint senses may be affected. Just as with the motor lesions the characteristics of the sensory lesions are their topography. Camus and Cézary and others have pointed out that in the area supplied by an affected root the sensory disturbances are not everywhere the same; in some parts there may be simply diminution of sensibility, in others true anaesthesia, or there may be a dissociation of sensory disturbances. Head and Campbell have shown that herpes zoster limited to the area of skin supplied by the affected root may occur. Langevin has described exanthemata with root distribution, and Ramon, Grenet, and Delille have observed purpura similarly distributed. In a certain number of these cases in which lumbar puncture has been carried out the cerebro-spinal fluid has shown a marked lymphocytosis, a certain sign of a meningeal lesion and therefore a confirmatory sign of a radiculitis. Clinically, some cases set in extremely abruptly and without premonitory symptoms; more often, however, a slower progress occurs, transitory pains first appear and later become permanent as the disease becomes established. Either the cranial or the spinal nerve roots may be affected and in the former case the fifth and the seventh nerves are especially liable to be involved. With brachial plexus lesions two forms occur, a total radiculitis (Duchenne-Erb type), and an inferior radiculitis with oculo-pupillary signs (Déjerine-Klumpke type). In the lower limbs there may be sciatic pain of root origin or pain of cauda equina distribution. Either one or many roots may be involved and consequently an infinite variety of forms may occur. Pure

motor and pure sensory root lesions are exceptional and most often a mixed form occurs. Radiculitis is diagnosed by the topographical distribution of sensibility and motor disturbances, and can therefore be distinguished easily from multiple neuritis. From lesions of the spinal cord, such as haematomyelia, it may be very difficult to distinguish, and from syringomyelia, and takes it to be distinguished by an absence of all other signs pointing to these diseases. Pathologically radiculitis should be limited to lesions of an inflammatory nature involving the nerve roots from their emergence from the cerebro-spinal axis to the foramina through which they pass. By this means are eliminated such lesions as traumatic injury, rupture, and tearing of the roots. It may occur as a primary affection or more usually as an effect on following meningitis, polyceritis or a spinal lesion. As to the causes of the condition, any infection can give rise to it and especially syphilis, and this particularly in radiculitis of the lower spinal roots. Next to syphilis, the commonest cause is tuberculosis, either a meningitis or caries of the spine. Gonorrhoeal conjunctivitis, cancer of the nerve roots, and alcoholism are also noted as causes. With regard to treatment, considering the frequency with which syphilis is associated as the cause, antisyphilitic treatment should be carried out with vigour, and in chronic cases surgical interference may be necessary.

SURGERY.

64. The Removal of a Cerebral Tumour.

IN publishing the details of a case of fibro-sarcoma of the left island of Reil and first temporal lobe of the brain which was treated by operation, H. Oppenheimer and F. Krause discuss many points of interest in connexion with the diagnosis of cerebral tumour and with the symptomatology of cases dealt with surgically. The patient was 37 years of age, and complained chiefly of pain over the left eye and left temple. Other symptoms were loss of memory, defect of speech, giddiness, thirst, and depression. During a stay in a sanatorium attacks of severe headache, vomiting, and slowness of the pulse were seen. Lumbar puncture only revealed a slight increase of the pressure of the cerebro-spinal fluid. The speech defect was chiefly a sensory and amnesic aphasia. Reading was possible but mechanical: the patient did not understand what she read and there was paralexia. On trying to write she mixed up the letters. There was no hemianopia. On examination of the retinae, double stasis of the papillae, more marked on the left than the right, was detected. There was tenderness and dullness on percussing the left temporal region. From these signs and symptoms Oppenheimer made the diagnosis of tumour in the left hemisphere, probably in the left temporo-sphenoidal lobe. Krause operated, the procedure being carried out in two stages. The upper left temporal region was incised and a skin-bone flap measuring about 80 mm. in each direction was reflected. The dura mater scarcely pulsated and was tense, and through it a hard mass of about the size of a finger-nail was felt. This corresponded to the beginning of the Sylvian fissure. The second stage had to be undertaken on the following day on account of the increasing intracranial pressure. Consciousness had gradually diminished during the night, and the second operation could be performed without any anaesthesia. On opening the dura mater, a small adherent portion of the size of a pea was found. This lay superficial to the resistance, and the adherent portion of the brain was found to form a prolongation of a more deeply situated mass. The latter was covered above by the operculum and below by the first temporo-sphenoidal convolution, and was presumably pushing the island of Reil medianwards. It was shelled out with the finger. It measured 60 mm. by 56 mm. by 43 mm. The vascular attachments were few and easily dealt with. The bed of the tumour was plugged to arrest the bleeding, and the flap was replaced. On the evening of this day the patient was found to be speechless: the right arm was completely paralysed, and there was right-sided facial paralysis. The right leg was spastic. There was deviation of the eyes to the left. During the following days only interjections were uttered, the mind became considerably clearer, but severe general disturbance gave rise to anxiety. The speech improved considerably at the end of a week. The paralysis of the right arm and facial muscles persisted at first, but Krause predicted that it would pass off. She continued to improve from this time onwards, and in the course of the following weeks the power returned in the right arm. The speech remained highly deficient. Two months later it was found to be necessary to remove some

protruding brain tissue. Six months later fresh cerebral symptoms led to a further operation, at which a tumour was removed, which the authors do not regard as a recurrence, but as a piece of the original tumour which had been left behind, and which had taken on fresh growth. The patient recovered well after this, and at the date of the report presented the appearance of a normal person. Her speech, however, was still defective, and her power of reading and writing was still limited, but these defects were improving daily. All the other cerebral symptoms had disappeared.

65. Prostatectomy.

PACHET (*Arch. Proc. de Chir.*, No. 12, 1908), who has performed 113 prostatectomies, advocates Freyer's operation, which, he holds, gives satisfactory immediate results, and subsequently affords perfect relief. He does not agree with those surgeons who regard it as a formidable method, and holds that the high rate of mortality noted by some operators is the result of neglect of certain technical details. In the first place, the bladder should not be freely exposed and incised, and the surgeon should be content with an opening in the vesical wall just large enough to admit the index finger. The enucleation, which is carried out "in the dark," and simply under control of palpation, should be effected gently, regularly, and methodically, commencing close to the vesical orifice of the urethra, over the culminating point of one of the lobes, and pursued forwards on either side, and afterwards, in a backward direction, at first over the superior half of the adenomatous mass, and finally along the inferior half. The author, who attaches much importance to the effective arrest and control of the bleeding after this operation, is guided in his practice by the method adopted by accoucheurs for arresting haemorrhage and preventing infection, of clearing the uterine cavity of clots and pieces of membrane, and of causing contraction and close apposition of the uterine walls by massage. After the enucleation of the prostate, the vesical cavity is gently washed out with hot water, and after removal of blood clots the walls of the cavity previously occupied by the enlarged gland are compressed between one finger in the bladder and another finger introduced into the rectum. Objections are raised against the use of gauze and of the siphon tube in drainage of the bladder, preference being given to the short and wide tube used by Freyer. This, it is stated, should not project into the vesical cavity for more than 2 centimetres. In cases in which the prognosis of prostatectomy is rendered very unfavourable by extreme debility, by digestive trouble, and by infection of the urinary passages, the author has obtained successful results from the performance of the operation in two stages, the enucleation of the gland being postponed for two or three weeks after the bladder has been opened by suprapubic section.

66. Local Anaesthesia in Major Surgery.

WINFIELD SCOTT SCHLEY (*Med. Rec.*, December 19th, 1908) advocates the more extended use of local anaesthesia in surgery. Many cases, he says, can be operated on by this method that would be impossible under general anaesthesia on account of heart, lung, or kidney lesions. Shock is much less by this method, there is absence of gastric and respiratory disturbances, and a much more agreeable post-operative period is obtained. This method must be used in selected cases, the character of the disease, of the patient, and the surroundings being factors that affect the choice. The author has done several abdominal operations successfully under local anaesthesia, of which he gives a detailed account. Gentleness of handling of the tissues is necessary. The patient feels no pain, and is not made nervous by the technique if properly managed. A very small amount of ether may be needed in some cases, for its mental effect chiefly. The peritoneum and intestines are practically devoid of sensitiveness when no inflammatory condition is present. One hour before operation a small dose of morphia is given. Novocain combined with adrenalin is used for injections into the skin along the line of incision. At intervals of $\frac{1}{2}$ in. to $\frac{3}{4}$ in. along this line the needle is inserted perpendicularly and injections made. The tissues remain dry and bloodless, and haemorrhage is saved the patient. The operation is begun after fifteen minutes. No bad effects are ever experienced.

OBSTETRICS.

67. Dilatation of the Os in Placenta Praevia.

HANNES (*Mediz. Klinik*, July 12th, 1908) opposes figures of cases observed by him during the last thirteen years to those of Hammerschlag. The latter, who recommends

bringing down a foot, had, in 191 cases, a mortality of 6.3 per cent. mothers and 84 per cent. infants. He mentions that Freund's mortality is given as 10.1 per cent., and Zweifel's as 7.8 per cent. Hannes found that among 119 cases of total placenta praevia, where dilatation of the os was employed, the mortality was only 5 per cent. mothers and 48.8 per cent. infants. He employs dilatation in all cases of total placenta praevia; in lateral placenta praevia (1) when the child lies transversely, (2) in head or breech presentations, when, after rupture of the membranes, haemorrhage does not cease, or pains are weak or absent. The bag is introduced through the placenta by boring through the latter with the finger or some blunt instrument. Thus introduced, filling of the bag does not cause further separation of the placenta, as would probably be the case were the bag introduced between placenta and uterus. Braun's vaginal dilator is used, and must be as big as a child's head when filled, so that when expelled the passages shall be wide enough to permit the passage of the head. It must therefore be capable of holding 600 c.cm. of fluid. Good rhythmical pains are stimulated by the pressure of the bag on the cervical ganglion. Traction should be exerted by a weight corresponding to the amount of fluid injected, but not greater than 600 to 700 grams; the object of this is merely to fix the bag immovably in place. Among out-patients a patent beer bottle, half-filled with water, has proved serviceable. Too forcible traction may cause premature expulsion of the bag in a sausage-shape, due to the formation of a diverticulum or to a cervical tear. Dilatation of the os is an easy operation; the bag can be passed when the os will admit one finger. On expulsion of the bag, delivery can be effected, if necessary, by turning. Of the 6 deaths, 2 were from air embolism after satisfactory delivery, 1 from uncompensated morbus cordis in the puerperium, 1 from anaemia, 1 from cervical tear (in the early days of the use of this method), 1 from pyaemia four weeks after delivery. Puerperal infection occurred in 0.8 per cent., whereas Hammerschlag lost 1.6 per cent. from this cause. This method is the best for the mother, and for the children the results are far better than are obtained with Hammerschlag's method. The danger of fatal pressure on the umbilical cord is equal in both methods, and in boring through the placenta there is a danger of wounding a large fetal vessel. The diminution in the contents of the uterus by bringing down a foot adds to the danger of the child.

68. Removal of Hypertrophied Mammæ in Pregnancy.

WISSHAUPT (*Prager med. Woch.*, No. 26, 1908) reports the history of a woman aged 28, who was pregnant and suffering from extreme hypertrophy of the breasts. Three years previously the disease began in the fifth month of her second pregnancy and advanced so quickly that two months later she became too weak to be able to leave her bed. Premature labour was induced, and the breasts diminished considerably in size afterwards. Wisshaupt was consulted by the patient in the fourth month of her next pregnancy. She suffered badly from a recurrence of the hypertrophy. The breasts hung down to the umbilicus; the right measured 29 in. in circumference, the left over 31½ in. Operation was considered advisable, and both breasts were removed; the right weighed 12½ lb., the left, which was amputated eight days later, was over 14½ lb. in weight. Pregnancy continued after the second operation. The disease of the breast proved, on microscopical examination, to be pure hypertrophy. This appears to be the second instance of operation during pregnancy for the removal of breasts hypertrophied as a complication of that physiological condition. The first operation of the kind (Foges) was reported in 1901.

GYNAECOLOGY.

69. Menstruatio Praecox: Hypernephroma of Ovary.

GAUDIER (*Echo Méd. du Nord*, July 26th, 1908) publishes a report of an operation on a female child aged 4 years where, as in Naeck's case (*EPITOME*, October 24th, 1908, No. 247), menstruation had been established and other signs of puberty were observed. The child was very hairy, the labia minora protruded beyond the labia majora and were strongly pigmented. The mammæ were 4 in. in diameter and the nipples had a distinct areola and area of dilated veins as in pregnancy. For three months there had been free menorrhagia and metrorrhagia between the periods. The abdomen had been enlarging for about four months. A freely movable, smooth tumour of the size of a big orange

could be defined; it was successfully removed. Its surface was pearly white, it was solid and seemed to be an adenoma, but on microscopic examination it was found to be made up for the most part of true adrenal tissue. It must have developed from an accessory suprarenal body in the parenchyma of the ovary, which had undergone hypertrophy. Gaudier notes that Marchand described in 1883 the first recorded case of accessory adrenals in the broad ligament, and Marchetti the first known instance of accessory adrenals in the ovary. They are usually detected in youth and tend to undergo atrophy in the adult.

70. Puerperal Abscess communicating with Bladder: Utero-Intestinal Fistula.

LE JEMTEL (*Revue de Gynéc. et de Chir. Abdom.*, July-August, 1908) took charge of a patient suffering from some obscure mischief of puerperal origin, possibly the result of a perforated wound of the uterus caused by the curette. There appeared to be an abscess opening into the intestine and vagina, and in addition faeces passed out of the os uteri, whilst the urine was mixed with pus. The abdomen was opened. A wide rent was found in the posterior wall of the bladder communicating with a cavity full of pus. Le Jemtel did nothing further than to close the rent with a few points of catgut and to drain the bladder through the urethra. He refrained from exploring by dissection the utero-intestinal fistula. At the end of one month the patient was not only cured of her bladder complaint, but also of the fistula, which had closed spontaneously.

THERAPEUTICS.

71. The Treatment of Burns.

PELS-LEUSDEN describes the methods now in use in the Berlin Charité in the treatment of burns (*Deut. med. Woch.*, November 26th, 1908). Before determining on the prognosis of a burn, it is necessary to consider the extent of the surface involved. When more than one-half of the surface of the body has been burned, the patient nearly always dies. Burns involving one-third of the surface may also lead to death. Next, it is necessary to determine the degree of the burns. He emphasizes that burns may appear to be of the first degree, but later show the formation of blisters, or even of scabs. The third point to be taken into consideration is the time which has elapsed between the burning and the examination. The effect of burns on the patient is manifested in general and local symptoms. No general symptoms occur in burns of small extent, but when a considerable area of skin has been involved certain disturbances are seen. The most apparent of these are those of the heart, kidney, and brain. Eppmann has shown that the effect of the heat on the skin produces toxic substances. These substances having been absorbed should be got rid of as soon as their presence is recognized. The cardiac activity is depressed, the pulse becomes rapid and very small, and the vascular tension is lowered. Haemoglobinaemia and haemoglobinuria are seen in many cases, the temperature sinks, and other symptoms indicate an intense toxic action. It is therefore necessary to give digitalis and large quantities of fluids. As the patients are usually thirsty no difficulty is experienced in getting them to swallow strong coffee and tea, with brandy and champagne. Repeated enemata of physiological saline fluid (100 c.cm. in each), or if the blood pressure is sinking intravenous injections of the same, often do good. This, however, should not be carried out in elderly patients until vomiting sets in and delirium or drowsiness threatens. He does not claim that this treatment will save patients for certain, but believes that in a number of cases with doubtful prognosis it acts well. Morphine must be given to allay pain and to quiet the patient, who often suffers severely either from the fear of impending death or from anguish in having been careless. The general symptoms must always be treated first, and it should be remembered that the treatment of the local condition may increase the shock. As a rule the general symptoms pass off in five or six days, but death has been seen after eight or even ten days without sepsis or duodenal ulcer being present. Local treatment of burns of the first degree is unimportant. This, however, is not so in burns of the second or third degree. The object aimed at is to avoid infection of the wound. First the burned area must be thoroughly disinfected. This is extremely painful and cannot be undertaken without some form of anaesthesia. When the burn is not extensive, a local anaesthesia by Hackenbruch's method suffices; in other cases a conduction anaesthesia may be employed, or lumbar anaesthesia should be resorted to. In extensive

turns of the head or of the body a general inhalation anaesthesia is necessary. Ether is better than chloroform. The vesicles or bullae are opened, and the whole surface is well washed with hot water, soap, and a brush for ten minutes. Then alcohol and perchloride of mercury solution is applied for two minutes, and, lastly, the wound is covered with a gauze dressing, with a thick layer of absorbent wool, and another of non-absorbent wool. This method was introduced by Tschmarke. The secretion of the wound is often extremely free, and it then becomes necessary to change the wool from time to time, but not the gauze. The exclusion of air usually relieves the pain. After from ten to fourteen days the whole dressing is spontaneously cast off. The wound is then found to be epidermizing well, and scars resulting from this treatment are usually satisfactory. When the burn is first seen after the lapse of some time, and especially if the surface is not free from infection, Bardeleben's bismuth dressing is to be recommended. Alcohol poultices may be applied when distinct infection has already taken place, and abscesses or phlegmonous inflammations require special treatment. Large denuded surfaces can be cleaned by means of a permanent bath, but care of the heart must be exercised if this is employed. The skin should be well smeared with a fatty ointment to prevent maceration. In the process of healing splints may be required to prevent contractures of joints, and early injections of thiosaniline or fibrolysin will be found useful to obviate contraction of scars in the skin, etc.

72. Osteomalacia Treated by Adrenalin Injections.

REVANDI (*Gazz. degli Osped.*, November 15th, 1908) records a case of osteomalacia successfully treated by adrenalin injections in 1906, cured at the time, and remaining well since, so that she was delivered without difficulty of a living child in July, 1908. The woman was 33 years old, and first began to notice symptoms in her seventh pregnancy (tiredness in the erect posture, difficulty in walking, pains in the pelvic girdle). In her eighth pregnancy her symptoms became so exaggerated at the eighth month that she was admitted into hospital; at that time she was compelled to keep her bed; the clavicles, ribs, and pelvic bones were swollen and tender, and the pelvic measurements reduced from incurving of the bones. Ordinary treatment seemed to do little good, and Caesarean section was contemplated, but Professor Bossi determined first to try the effect of hypodermic injection of Parke Davis 1 in 1,000 adrenalin solution, of which 3 c.cm. was given morning and evening. Almost at once relief from the pains in the bones and the consequent restlessness and insomnia was obtained. The dose was ultimately raised to 2 c.cm., and injections, with occasional short interruptions, were given from December 16th to January 6th, when labour set in. Twins were delivered with the help of forceps, and the puerperium was uneventful (save for a slight mastitis). The patient left the hospital February 27th, cured. Since then she had one miscarriage at two months, and a full-term child born in July of 1908 naturally and without any of the disturbances which had been so marked in the seventh and eighth pregnancies. Experimentally the author has found that with x rays one can see a certain degree of osteoporosis in the bones of animals deprived of the suprarenal glands. The interest of the case consists not only in the cure but in the permanent character of the cure. No injections were given after she left the hospital. The author suggests the possibility of similar treatment in rickets.

73. Treatment of Angioma by Congealed Carbon Dioxide.

SAUERBRUCH (*Zentralbl. f. Chir.*, No. 1, 1909) reports very favourably of the results obtained from the treatment of cutaneous angioma by the direct application of congealed carbon dioxide. This method, which was brought under the author's notice by A. I. and E. Oxner of Chicago, will, it is stated, be found a simple and efficient means of dealing with both superficial naevi and also with small cancerous growths of the face. The following description is given of the technique of this treatment: From a cylinder of carbon dioxide, such as is used in making frozen micro-sections, a fairly strong jet of the gas is played on to a piece of cotton-wool; the rapid evaporation of the liquid dioxide causes intense chilling, which condenses a portion of the gas into a snowy powder with a temperature of -70° C. Some of this solidified gas is applied to the surface of the naevus, where it remains from ten to thirty seconds. The intense cold causes extreme contraction of the blood vessels and anaemia of the growth. This is repeated once or twice at the same sitting, the white flakes being applied to different parts of

the vascular surface. No dressing is placed over the seat of this operation. The treatment is renewed at intervals of from eight to ten days until the tumour has completely disappeared. In its cosmetic results this method, it is stated, compares favourably with those that are usually practised, and, moreover, is free from pain.

PATHOLOGY.

74.

Haemophilia.

ESMEIN (*Arch. des Mal. du Cœur des Vaisscaux et du Sang*, September, 1908) quotes the following case of haemophilia and gives the result of a pathological examination. The patient, 16 years of age, came under observation for recurring and rebellious epistaxis which had led to extreme anaemia. There was no family history of haemophilia: the skin was pale, the mucous membranes blanched, and slight oedema was present about the malleolar regions. The liver and spleen were slightly enlarged, the other organs appearing normal. The blood contained 2,000,000 red cells per cub. mm.; there was a slight polynuclear leucocytosis together with some myelocytes and nucleated red cells. The coagulation time of the blood was retarded, varying from thirty minutes to an hour. There was no local lesion present in the nose or pharynx to explain the epistaxis. Soon after coming under observation profuse nose bleeding, together with bleeding from the gums and petechial haemorrhages into the skin, occurred, and death took place. At the post-mortem examination lesions were found in the liver, spleen, bone marrow, and kidneys. The bone marrow was red throughout, and was of such a character as is found after haemorrhage. The spleen was much in the same condition, and its section stuffed with debris of red cells and blood pigment; the liver appeared fatty and was smooth, its general yellowish appearance being marked with small irregular red zones. On microscopical examination a section of the liver showed that normal hepatic tissue was present around the portal spaces only: around the hepatic veins were found large masses of necrosed liver tissue, the hepatic cells here having disappeared, and having been replaced by masses of brown pigment, of blood pigment, and of fat globules. In this debris were seen numerous polynuclear leucocytes. A slight amount of sclerosis was also found. The kidneys were somewhat sclerotic. The author believes that in this case the lesions found in the liver were the cause and not the result of the haemophilia.

75.

Tuberculous Infection through the Alimentary Canal.

MAZYCK P. RAVENEL and JOHN REICHEL (*Proc. of the Path. Soc. of Philadelphia*, 1907), on tuberculous infection through the alimentary canal, report the results of experiments conducted upon 65 guinea-pigs. The problems of the experiments were to determine the ability of tubercle bacilli to pass through the intestinal wall of healthy guinea-pigs, and the time required for them to reach the lungs. The plan of Schlossmann and Engel was in a general way closely followed. Young guinea-pigs were used which had been deprived of food for some hours before they were operated upon. The stomach being raised through an abdominal incision, an emulsion of tubercle bacilli of known virulence was mixed with an equal volume of fresh heavy cream, and injected into the stomach. An extremely fine hypodermic needle was used, and special precautions were taken to prevent infection of the peritoneum on inserting and withdrawing the syringe. Of the 65 guinea-pigs, 10 were used as controls, 10 were killed after four hours, 12 after five hours, 8 after six hours, and the remainder were permitted to live for different periods, the longest being twenty-four hours. The lungs from each guinea-pig were removed, ground in a mortar with physiological salt solution, and injected intraperitoneally into a pair of healthy guinea-pigs. The experiments apparently show that tubercle bacilli passed readily and quickly through the intestinal wall, and reached the lungs in a short time through the thoracic duct. There is doubt as to the accuracy of the method followed; for infection occurred not only through the mucous membrane of the intestine, but also directly through the wound in the stomach caused by the hypodermic needle, and it is possible that in spite of the precautions taken tubercle bacilli were deposited on the edge of the wound when the needle was withdrawn. It appears that inoculations into the alimentary tract should be made without the production of a fresh wound of this tract, in order to obtain results not open to criticism.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

76.

Angina Pectoris.

Two varieties of angina pectoris are usually recognized—the true angina or “angina major,” the result of definite anatomical changes, and generally of the nature of arterio-sclerosis, and the false angina or “angina minor,” the result of functional disturbance without anatomical substrata. The attack of true angina occurs suddenly but not spontaneously. Josué (*Arch. des Mat. du Cœur des Vaisseaux et du Sang*, October, 1908) says there is always to be found a cause which precipitates an attack, such as fatigue, walking, and especially walking against the wind, digestive processes, straining at stool, mental emotions; fear of an attack may actually precipitate one. With the onset of the attack there occurs pain in the heart and behind the sternum of an extremely painful constricting nature. The pain radiates into the left arm and sometimes into the neck and auricular region, and the region of the cervical plexus. Accompanying the pain there is a terrible mental anguish; the patient is fully conscious of the danger which threatens him, and avoids making the least movement for fear of increasing the duration of the paroxysm. He does not speak nor complain. In some cases the pain is less intense, but the characteristic mental anguish shows itself, as it does in those cases in which pain may be completely absent. During the attack the face is pale, respiratory movements are free and auscultation and percussion shows no disturbance of the respiratory apparatus. The attack lasts from a few seconds to several minutes, when the pain ceases abruptly. In some cases abundant clear urine is passed in the attacks. The attacks may occur only at long intervals, or they may become frequent, several occurring during day or night, or the attacks may indeed become more or less continuous. Death may occur during the first attack or during subsequent attacks; generally sudden, death may occur less quickly through dyspnoea or from a rapidly oncoming oedema of the lung; in other cases the patient dies from a giving out of cardiac power in arterio-sclerosis. Angina minor occurs in hysterical and neurasthenic subjects or in patients suffering from organic nervous diseases, such as tabes. In exophthalmic goitre false angina pectoris sometimes occurs, as it does in tobacco intoxication. The attacks come on generally at night, and are not precipitated by fatigue, efforts, etc., as in true angina, but seemingly spontaneously. The patient complains of violent burning in the chest, she feels as if her heart were too large for her chest, which appears swollen. The precordial region is markedly hyperaesthetic. The face is cyanosed and often covered with a cold sweat; the patient is agitated and restless, respiration is difficult, and the extremities are cold and cyanotic. The attack does not cease rapidly and abruptly, as in true angina, but lasts for half an hour or longer. Large quantities of urine are passed, and the symptoms gradually pass off. The attack never ends fatally. Between typical cases of true and false angina it is very easy to distinguish, as the author remarks, but there are intermediate cases in which it is difficult if not impossible to do so. With regard to the pathology of angina pectoris, the general idea is that it is the result of an anaemia of the myocardium caused by complete or incomplete obliteration of the coronary arteries. The blood supply to the cardiac muscle through the narrowed coronary arteries is sufficient when the patient is resting, but insufficient for the needs of the cardiac muscle when the patient exerts himself. The upholders of this hypothesis as to the coronary artery obstruction being the cause of angina think that attacks of false angina are the result of a simple spasm of the nutrient vessels of the heart. The coronary artery theory of angina is, however, not borne out by anatomical and physiological facts. Cases have been published in which typical attacks of true angina have occurred, and in which cases at autopsy neither obliteration nor stenosis of the arteries of the heart have been found. Also obstruction or narrowing of the coronary arteries has been found *post mortem* in persons who have never suffered from attacks of angina. After ligation of one of the coronary arteries in an animal it is found that the cardiac muscle supplied by the ligated vessel ceases to contract, and complete arrest of the heart follows ligation of both coronary arteries. These results are quite different to what occurs in angina

pectoris, in which the heart continues to beat normally. Another view is that true angina pectoris is the result of a neuritis of the cardiac plexus of nerves, which in its turn is the result of aortic lesions (Lancereaux, Peter). This theory explains readily the radiations of the pain, but does not explain how it is that the attacks are precipitated by certain occasional factors, nor why it is that the attack ceases as soon as the patient remains at rest. Merklen thinks that a subacute distension of the heart plays a rôle in the attacks of angina pectoris, and, whilst admitting that this factor may possibly have a share in bringing about the pain in certain cases, in others it can have no influence. According to Roudot, and Gilbert and Garnier renal insufficiency is the real cause of anginal attacks. With regard to the state of the arterial tension in cases of angina, Déja-Dunin found that in cases of arterio-sclerosis, attacks of angina occurred in 46 per cent. of cases with an arterial tension lower than normal, and in 18 per cent. of cases in which there was increased arterial tension. He further found that there was no difference in the symptoms and prognosis between the two classes of cases. On the other hand, Pal and Rist and Krantz have noticed that even if the arterial pressure be normal or subnormal between the attacks of angina, the pressure rises the moment the attack occurs, and Pal considers angina as a form of vaso-constrictor crisis. Vaquez says that abrupt distension of the aorta, which is already diseased, sufficient to cause an accidental increase of pressure, is the cause of anginal attacks. In the author's opinion anginal pain is the pain of a diseased aorta, and he likens the pain to that occurring from intestinal, hepatic, and nephritic colic where disturbances in the intestine, liver, or kidney exist. In the case of aortic pain, however, the patient unconsciously recognizes the grave danger of disease of so important a vessel. These painful attacks occur when the disease is localized to the first part of the ascending aorta near its origin. The influence of movement, emotion, etc., in precipitating an attack of angina is seen when one remembers that these factors cause a rise of arterial pressure, the aorta becomes more distended, and pain then occurs. This theory explains how it is that angina occurs so readily in patients with a high arterial pressure such as is found in renal insufficiency.

77.

Hysterical Fever.

MÜRCHEN (*Berl. klin. Woch.*) states that undoubtedly rise of temperature to the highest degree possible occurs for which no explanation can be found in any diseased organ. Mixed forms also occur where an existing organic fever rises considerably owing to the intervention of nervous causes. Presumably the rise of temperature is of vaso-motor origin. The cases described are met with in individuals with marked vasomotor neuroses, especially hysteria. This nervous fever is further distinguished from one of organic origin by the irregular type of fever, its origin and disappearance in connexion with psychico-nervous occurrences, the very slight disturbance of the general well-being even with the highest degree of fever, the hardly altered condition of the pulse, nutrition, breathing, etc., the failure of antipyretics and the positive action of baths and suggestive treatment. Differential diagnosis: Phthisis, typhoid, meningitis, influenza. A false diagnosis of phthisis is most often made; it is extraordinary how often one finds a history of lung trouble of which later no further mention occurs; some authors speak of pseudo-phthisis. In one case osteo-myelitis was thought of.

SURGERY.

78. Gland Puncture in the Diagnosis of Syphilis.

PREIS (*Pester Med.-Chir. Presse*, November 8th and 15th, 1908) has been able to demonstrate the *Spirochaeta pallida* in nearly 100 per cent. of cases of syphilis in the secondary latent stage. In all of 60 doubtful cases, which gave a positive result, clinical evidence of syphilis appeared later. The technique is so simple that every practitioner can undertake it, and it is thus no longer permissible to allow a diagnosis to remain in doubt, or to wait for the appearance of secondary symptoms. Gland puncture should be used in all cases where, for any reason, examination of the ulcer serum proves negative. This is likely to be the

case if the ulcer is partially or completely resolved, if it has been treated with caustics, or if it is disintegrating. The author has never failed to find the *palidra* during the period between the first typical hardening of the glands and the first eruption (six to ten weeks). A small syringe, such as is used for injections, is employed; the skin over the gland is shaved, cleansed, rubbed energetically with ether, and then drawn away from the gland as far as possible, so that on withdrawing the needle no superfluous exudation from the loose tissues shall enter. The needle is plunged as obliquely as possible in the long axis of the gland, and its point is moved about, so as to obtain exudation from various parts. Aspiration should be vigorous. The liquid obtained is then syringed out at once on to a glass slide, and smeared along this by the edge of a second slide. This should be done as speedily as possible. No attempt to fix should be made, but a solution of 20 to 25 drops of Giemsa's solution in 15 c.cm. of distilled water should be at once poured liberally on to the slide. The slide is then warmed over a Bunsen or spirit flame until steam begins to rise, when the solution is poured off. This process is repeated till the stain has all been used, and the whole procedure should be as rapid as possible. The slide is then washed under the tap and dried with blotting paper. The preparation should now be examined under a low power in order to see if the red blood corpuscles are well stained. If this is the case (and if otherwise staining should be repeated), a part where the red blood corpuscles show well should be chosen, and this part examined with the immersion lens. No spirochaetes have as yet been found in syphilitic glands except the *palidra*; and the author has examined the glands in cases of carcinoma of the buccal mucous membrane and of gangrenous ulcer and found no single spirochaete. Preiss gives notes of 3 doubtful cases in which gland puncture cleared up the diagnosis. This method is superior to Wassermann's reaction, in which only 56 per cent. of the cases in the secondary latent stage give a positive reaction, which is also complicated, and in which mistakes may occur on the positive side—a result never seen in gland puncture. Wassermann's reaction should only be used when spirochaetal examination for any reason is inadvisable.

73. Mechanical Treatment of Paralysis of the Shoulder.

DAVID SILVER (*Amer. Journ. of Orthop. Surg.*, November, 1903) says the disability in paralysis of the shoulder is the result of direct sinking of the head away from the socket, insecurity of the head, and contraction of unaffected muscles. That damaged nerve cells may recover sufficiently to functionate, but in the meantime the muscles are incapacitated by overstretching and atrophy from disease, is well known. If these evils have not been avoided by timely measures, it is still possible at a later stage to do some good by maintaining the paralysed muscles in a position of maximum relaxation, and thus permitting retraction to take place. In the application of this principle of treatment to the shoulder the author makes use of a modification of Monk's wire splint, putting up the arm with hand supinated, elbow flexed, and palm resting upon the top of the head. Three cases are reported in which the method was followed by good results. Since the method is a conservative one, its use is recommended in all cases not known to be completely paralysed. While in some cases the paralysis is so extensive that the remaining power will be insufficient, even when developed to the highest degree of efficiency, to maintain contact between the head of the humerus and the glenoid, in others it may be sufficient to maintain contact and no more, yet there are still others with a greater degree of recovery of the nerve lesion, in which a varying amount of active abduction will be secured. The use of the method is also recommended as a preliminary measure to muscle grafting.

83. The Treatment of Ruptured Kidney.

MORESTIN (*Bull. et Mém. de la Soc. de Chir. de Paris*, No. 36, 1908), in a report on a case communicated by Prodet, in which extensive laceration of the left kidney causing abundant haemorrhage was successfully treated by suture of the injured organ, discusses the indications for direct surgical intervention in similar instances. While acknowledging that in most instances renal contusion may be cured by rest and simple means of treatment, the author of this report holds that when there is free and persistent bleeding with a large perirenal haematoma, and the condition of the patient is such as to excite much anxiety, the surgeon should not hesitate by the simple and harmless procedure of a lumbar incision

to expose the injured kidney with the views of dissipating doubt, of arresting the flow of blood, and of protecting the patient against remote complications. Nephrectomy, which, it has been stated, is practised too frequently and without just cause in cases of renal injury, should, it is argued, be reserved for those extreme forms of traumatism in which the kidney has been either completely crushed or torn away from its hilum. In most cases, Morestin asserts, the condition of the ruptured kidney will permit a conservative operation. Suture of the lacerated kidney is possible, and, indeed, a relatively simple measure. It may enable the surgeon to re-establish the shape of the organ, and will suffice to arrest bleeding. It is pointed out, however, that the application of sutures to a lacerated kidney will not prevent but rather favour the formation, between the apposed surfaces of torn renal tissue, of cicatricial septa which will tend to keep the fragments anatomically distinct. Moreover, the tension of the sutures may modify the functional value of the preserved organ. For these reasons the use of the suture would be indicated, the author thinks, only in those cases in which the laceration is not extensive. If the kidney be much torn, but still in a condition favouring conservatism, it might be well, it is suggested, to arrest the bleeding and to treat the injury by simple packing. It remains uncertain whether the conservative treatment of ruptured kidney which is so satisfactory and free from danger in its immediate results, is likely or not to lead in course of time to any serious disturbance of the function of the retained organ.

OBSTETRICS.

81. Artificial Interruption of Pregnancy.

IN developing the thesis that the practitioner is justified in inducing premature labour under certain conditions. H. Fritsch (*Deut. med. Woch.*, November 19th, 1908) points out that no definite indications for this procedure can be set up, but that each case must be judged on its own merits. He regards it as a gross error to say that pregnancy should be interrupted in hyperemesis gravidarum, and just as great an error to say that it should not be interrupted. The objection to killing a fetus or to inducing labour before the fetus is viable is usually that the practitioner has no more right to sacrifice a life than any other man has. To this he replies that it is certainly criminal to sacrifice the life of the mother when she could be saved by the removal of the fetus, while if the pregnancy is undisturbed both mother and fetus will die. The skill of the practitioner is required to determine when this applies. He cites a case in Bavaria in which a medical man was found guilty of manslaughter by negligence in not performing laparotomy after rupture of the uterus and escape of the child into the peritoneal cavity. Neglect to do the right thing in obstetrics is just as culpable as doing the wrong thing. It is frequently stated that pregnancy may not be interrupted until all other means have been tried and have failed. Fritsch considers that this may lead to difficulties, inasmuch as "all other means" is a very wide expression. He prefers to lay it down as an axiom that pregnancy should not be interrupted until the patient has been carefully observed for a reasonable time in a hospital. He maintains that observation in the patient's house is incompatible with the proper trial of less radical measures. Two diseases are mentioned which may form indications for the interruption of pregnancy. These are hyperemesis and tuberculosis. He has been consulted five times during forty years in cases of hyperemesis, in which the only reasonable advice was to let the patient die as comfortably as possible. The lives might have been saved at an earlier stage by induced abortion, but it was too late. With regard to tuberculosis, it is necessary to recognize that some cases run a very rapid course and death ensues within a few weeks, while others are essentially chronic. Between these two extremes there are innumerable transitions. A careful selection of the cases is therefore necessary, and only experience can teach which cases will do well if the pregnancy is left undisturbed under otherwise favourable conditions, and which will do well only after abortion is performed. The only solid objection to artificial interruption of pregnancy in selected cases is the one that the mental effect on the patient, the pain, the loss of blood, and the subsequent febrile disturbances do more harm than the removal of the fetus does good. Fritsch admits that all this will detract from the usefulness of the procedure if the technique is bad. He points out that nearly all authors who write on this subject describe a different technique. He therefore

goes into some detail in respect to the technique which he has employed, and which has yielded him excellent results. He warns the obstetrician against rapid clearing of the uterus. It is very tempting to get the business over as quickly as possible, but it is very fatal to put this into practice. First, the patient is admitted into hospital. The advantages of this are: First, that the notes on the history of the case and the presence of a number of trained persons guarantee that the induction of premature labour is not criminal: in the second place, the observation in hospital permits of a better determination of the proper time when the pregnancy should be interrupted than in private houses. The bowels are opened, a "sitz" bath of lysol solution is given, and the patient is put to bed. During the course of twenty-four hours the vagina is irrigated three times with 2 litres of lysol solution, and the external parts are well disinfected. A suitable miniprina tent is then introduced into the cervix. The vagina is loosely packed with iodoform gauze. The external parts are covered with wet disinfectant dressings, which must be renewed after each soiling, and also from time to time. After twenty-four hours the patient is placed on her side, the tent is removed, and the vagina is irrigated. The membranes are then pierced by a uterine catheter, and the amniotic fluid is allowed to escape through the catheter. Long strips of iodoform gauze which have been dipped into ichthyol glycerine are then introduced into the uterus and amniotic cavity. In multiparae the whole ovum is often expelled rapidly after this without marked pain. As the fetus dies the decidua becomes spontaneously detached and the glycerine also calls forth contractions. After the whole ovum is expelled the vagina and uterus are irrigated and the patient is put back to bed. After about twenty-four hours no more blood comes away, and as a rule the patient can get up and leave the hospital on the second or third day. In some cases the uterus does not contract and fever sets in. This is not a sign of infection, but arises in all cases in which the fetus dies *in utero*. As soon as the membranes, etc., are detached the whole ovum can be removed by means of a curette or of ovum forceps. In this way the author obtains good results, never experiences hæmorrhage, and always places his patients in the best possible position for a complete recovery.

GYNAECOLOGY.

82. Treatment of Cancer of the Genital Organs in Woman.

FAURE (*Internat. Soc. of Surgery*, 1908) states that the removal of cancers of the vulva should always be accompanied by removal of the inguinal glands. If the vulvar carcinoma be situated medially the glands in both groins should be removed, and even when the vulvar growth appears to be limited to one or other side he thinks it is wise to remove the inguinal glands on each side. In cancer of ovary or Fallopian tube, both tube and ovary should be removed. With regard to cancer of the uterine body, the author thinks hysterectomy by the abdominal route far preferable to that by the vaginal route, as the former allows of complete removal of the diseased organ without laceration or tearing of it, as is inevitable when the vaginal method is adopted. In feeble patients, however, and in very fat patients, he thinks it is better to carry out subtotal hysterectomy and to leave the neck, provided that a sufficiently wide margin of healthy tissue can be removed outside the limits of the growth. In the case of cancer of the vagina the author discusses the treatment under two headings: First, cancer of the lower part, and secondly, cancer of the upper part. Cancer of the lower third of the vagina should be treated like vulvar cancer, whilst cancer of the upper two-thirds of the vagina should be treated like cancer of the uterine cervix. In cancer of the upper part of the vagina, removal by the vaginal route is, in the author's opinion, a very uncertain and insufficient method, and the abdominal route he considers the only satisfactory way. It is necessary to remove both the uterus and the upper part of the vagina, and the operation should be carried out just like an abdominal hysterectomy for cancer of the cervix. By the abdominal route one can separate the diseased vagina from the rectum, bladder and ureters, and the hypogastric arteries can be ligatured. Before commencing the abdominal operation, the wall of the vagina should be cut through in a circular way about 2 cm. below the lowest limit of the growth. Such an operation, although fraught with considerable immediate danger, will, the author thinks, give far better results than vaginal operations, which almost always end in recurrence and

death. With regard to cancer of the cervix, there is no doubt in the author's mind that abdominal hysterectomy is far superior to hysterectomy by the vaginal route. The abdominal operation has rendered possible a hysterectomy on a far larger number of cases than was possible when vaginal hysterectomy was employed, the statistics of Rosthorn, Doderlein, Schauta and Chrobak, Wertheim, etc., showing this. By the abdominal method one can remove the diseased parts far more surely and carefully than by the vaginal route, and the ureters especially can by the former method be carefully dissected; this is not feasible at the vaginal operation. Another disadvantage of the vaginal operation is that infected lymphatic glands are liable to be missed. Even in cases in which the extent of disease is limited, the author is of the opinion that the abdominal operation is still to be preferred, as, under these circumstances, the gravity of the operation does not exceed that of vaginal hysterectomy, and it allows of a far more complete inspection and examination of the extent of disease than does the latter. Vagino-perineal colpo-hysterectomy, as performed by Schuchard and Schauta, has given very good results, from 40 to 50 per cent. of their cases being cured; but, in the author's opinion, this operation, although superior to vaginal hysterectomy, has some of the same disadvantages; by this method the ureter cannot be freed from growth with the same ease and safety as in the abdominal operation, nor can the lymphatic glands be had access to. He considers this operation justifiable only in cases of well circumscribed disease; and, as the case mortality for this operation is the same as that for abdominal hysterectomy, for this and for the reasons given above he prefers the latter operation. Abdominal hysterectomy is in simple cases an easy operation; it affords the surgeon infinite resources in exploring the pelvis which no other operation does, and its only drawback is its gravity. But, as the author remarks, in treating such a mortal disease as cancer of the cervix, the operation which gives the best prospect of lasting cure should be carried out in spite of its gravity. In carrying out abdominal hysterectomy by the method of Wertheim the author nearly always ligatures the hypogastric arteries, as by this means excessive loss of blood is prevented and a more minute examination of the diseased parts can be carried out. To check bleeding from small vessels in the depth of the pelvis the author employs metallic ligatures, using Michel's forceps for this purpose. He is convinced that it is advisable to remove all lymphatic glands which can be felt easily, and especially those situated on each side of the pelvic wall near the bifurcation of the iliac arteries. Further than this he does not go, as to remove all the glands and cellular tissue of the pelvis is an impossible operation. With regard to the removal of the lumbar glands, the author thinks that if the lumbar glands are infected there are probably many others also involved, and that it is folly to think that one can remove all such glands. Large and extensive operations for the removal of all possibly infected glands renders the gravity of the operation much more severe, and may be the means of infecting the large cellular spaces and lead to septicaemia. For these reasons the author advises that only those glands which appear to be infected should be removed, these glands being those situated on the lateral aspects of the pelvis about the bifurcation of the iliac arteries. Vagino-abdominal hysterectomy the author has carried out thirteen times. The vaginal wall is incised circularly at a suitable height, the wall is separated from the bladder and rectum, and its edge sutured over the cervix, enclosing this. This being done, abdominal hysterectomy is carried out in the usual way. This preliminary separation of the vaginal wall allows the uterus to be well raised up from the pelvis during the abdominal operation, and the parts around the cervix can then be dissected with great ease. This preliminary vaginal section has also the advantage that by it the operator can easily know at what level he is to stop when dissecting in the pelvis. In conclusion, the author states that in simple cases with limited ulceration and a perfectly movable uterus the simplest and the best operation is pure abdominal hysterectomy; in more complicated cases and when the uterus is not freely movable, it is better, both for the safety of the patient and for the facility of operating, to have recourse to vagino-abdominal hysterectomy.

THERAPEUTICS.

Treatment of Carbuncles.

83. The treatment of large carbuncles is, according to Max Grasmann (*Deut. med. Woch.*, October 15th, 1908), one of the most difficult problems which the general practitioner

has to meet. A simple incision of an inch or so in length cannot serve any useful purpose when the pustule extends from the middle of the occiput to the upper dorsal vertebrae and from the one sterno-cleido-mastoid to the other. Poulitices also are not sufficient for such a lesion. The most certain method is excision. Kiedel first described a satisfactory method of carrying this out. The operation must be so planned that all the dangerous area is removed, that the general health does not suffer from the interference, that not too much healthy tissue be sacrificed, and that while the process of healing is rapid, the scar resulting becomes a smooth one. Various methods have been suggested, but the author considers that the one which he uses can be recommended. He makes a deep crucial incision over the carbuncle. The skin flaps thus made are dissected from the muscular fascia and packed underneath with gauze. Hot boro-salicylic acid solution applied on gauze is used for stopping bleeding and for plugging. The surrounding skin can be protected from burning by smearing with fat. The necrotic tissue is then removed partly with scissors and partly with forceps. A sharp spoon should not be used. When all the inflamed and necrotic tissue has been got rid of, a fresh hot boro-salicylic plug is applied and a large wet dressing covers the whole wound. The greater part of the necrotic tissue is cast off within a week of the operation and healthy granulations appear in the wound. The skin flaps are then brought into position by a few sutures, and the wound is rendered as small as possible. The only points in the treatment on which he lays emphasis are free and early incision from healthy tissue to healthy tissue across the carbuncle, free exposure of the necrotic tissue after the flaps have been protected, and plugging with hot boro-salicylic acid solutions. He has obtained excellent results in his cases with this method.

84. Intravenous Injections of Sublimite in Typhoid Fever.

CRISPOLTI (*Rif. Med.*, December 14th, 1908) reports two severe cases of typhoid where extraordinarily good effects were induced by intravenous injections of sublimite. In each case a marked feature was the high temperature and grave toxæmia. The treatment was inaugurated on the twelfth and thirteenth day of the disease respectively. In one case the temperature dropped after the first injection. In seven hours, from 40.3° C. to 37.2°, and after a temporary rise the next day to 37.9°; after a second injection it fell to normal and remained so to the end. In the other case an equally satisfactory result was obtained, but owing to two secondary and temporary rises of temperature three injections were necessary. Both cases recovered completely. With the fall of temperature there was a corresponding rise of blood pressure and improvement in the toxic symptoms. The dose was 1 centigram, and the author strongly advises that not less than this should be given: he has given 2 centigrams in some cases of syphilis. The effects were certainly highly beneficial in these cases and showed themselves chiefly in the reduction of the temperature, in the lowering of the rapidity of the pulse and respiration, in the rise of blood pressure and the lessened toxæmia. Probably these results were brought about by stimulating the greater and more active production of antitoxin substances.

85. Bromglidin.

H. BORUTTAU (*Deut. med. Woch.*, October 29th, 1908) states that while organic bromine compounds have been recommended in therapeutics, little has been made out with regard to the method of excretion or retention of the bromine. It is apparent from what has been written on this matter that bromine, when given in the form of the alkaline bromides, behaves differently to the way in which iodine in the form of alkaline iodides behaves. Iodine is not stored up in the organism, even when given in large doses. Bromine, on the other hand, is very slowly excreted, and to a considerable extent is retained. It has been found that chlorine is excreted in excess during medication with bromides, so that it has been assumed that the bromine replaces chlorine in the organism. Bromglidin contains 10 per cent. bromine. It is put up in 3 gram tablets. Boruttan studied the excretion of bromine when taken under varying conditions. After taking six tablets daily for four days—that is, 1.2 grams of bromine—he found that the urine contained the following quantities of bromine on the respective days: 0.171, 0.202, 0.217, 0.189, 0.099, and 0.017 grams, while traces were found up to the tenth day. Testing the conditions on animals, he found that rabbits behaved in a similar manner. Other experiments confirmed the find that the bromine of bromglidin is excreted, like the bromine of the alkaline bromides, extremely slowly, but that the initial excretion—that is, the excretion during the

first twenty-four hours—is higher than in the case of the bromide. He further found that the same physiological action was obtained by smaller quantities of bromine in bromglidin than in alkaline bromides.

86. Fulguration in Cancer.

K. SCHULTZE, writing from Bier's surgical clinic in Berlin, reports on the trials which they have made of the fulguration treatment of cancer, and comes reluctantly to the conclusion that its value is *nil* (*Deut. med. Woch.*, October 6th, 1908). Four cases of inoperable mammary carcinoma were selected for the treatment. At first a beneficial influence was seen in the carcinomata. The pain and discharge from the ulcerating surfaces lessened, and the general condition improved in some of the cases. It is, therefore, as good a palliative means as are Roentgen and radium rays and caustery. He gives short summaries of the four cases, from which it appears that one of the patients had already died after an apparent improvement lasting for eleven days; the second patient improved locally under the treatment, but a spread of the growth soon made itself visible and palpable; the third patient improved after the operation and fulguration, but after a time fresh growth took place, and the general condition became markedly worse; while the fourth patient also appeared to have been improved by removal of the greater part of the tumour and fulguration of the unremovable portions, but after a short time fresh nodules appeared, and the disease seemed to progress with undiminished energy. In spite of the good results claimed by some surgeons from this method, Schultze is forced to state that fulguration in his hands has been a complete failure.

PATHOLOGY.

87. Serum Reaction of Syphilis.

DURING recent times the clinical value of the Wassermann-Neisser-Bruck reaction in syphilis has been shown to be considerable, and it was therefore of importance when Much and Eichelberg reported early in 1908 that in a series of scarlatina patients, to which they had applied the reaction, complement was deflected in 40 per cent. These authors considered themselves justified in warning clinicians against attaching too great importance to a positive reaction. Bruck and L. Cohn (*Berl. klin. Woch.*, December 21st, 1908) considered that the clinical value of the reaction would only be lessened by this find, if confirmed, if it could be shown that the scarlatinal reaction persisted after convalescence. Several observers tested the serum of non-syphilitic children during an attack of scarlet fever and obtained negative results. While the authors do not question the correctness of Much and Eichelberg's results, they came to the conclusion that a positive reaction in scarlatina is not the rule but an exception, which is produced by some altered conditions, the nature of which is still unknown. Seligmann and Klopstock accidentally came across an interesting find. They obtained negative results in 13 scarlatina cases. After a longish interval they used the same extract and obtained positive reactions not only with scarlatinal serums but also with the serum of persons who were not suffering from scarlatina or syphilis. The antigen had obviously undergone some change. Others found that different antigens were capable of yielding positive reactions in scarlatina and syphilis. This would suggest that the reaction in scarlet fever is not identical with that in syphilis. In repeating the experiments with various antigens, the authors found that while all the antigens which they used gave uniform positive reactions with syphilitic serum, some scarlatinal serums gave positive reactions with one antigen and negative reactions with the others. It is therefore not correct to state that the syphilis reaction occurs in scarlatina, since it has been shown that the substance giving rise to complement deflection in scarlatinal serum is not identical with that giving rise to the reaction in syphilitic serum. They therefore claim that the clinical value of the syphilis reaction is not lessened by the find that scarlatinal serums may react positively with one antigen but not with others. Much himself has more recently admitted that this is so.

88. Phlyctenules after Calmette's Reaction

STARGARDT (*XXXI. Versammlung d. Ophth.-Gesell., Heidelberg*, August, 1908) finds that the phlyctenules which so often follow the use of Calmette's serum have the same characteristics as the ordinary phlyctenules described by Leber. Giant cells are present, but no caseation. Tubercle bacilli are not found.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

89. Grocco's Triangle.

GROCCO described this as an area of relative dullness taking the form of a right-angled triangle, to be found on the opposite side of the back to that on which a pleural effusion is present. Its inner limit corresponds to the line of spinal processes, its base to the lower limit of the thoracic resonance, and its outer limit is represented by a line drawn from the base rising obliquely to join the vertebral column in the neighbourhood of the upper limit of the pleural effusion. Grocco states also that the dullness increases as one approaches the base or the vertebral spines, and it is modified by the position assumed by the patient, diminishing when he lies on the side with the effusion. It is more definite when a right pleural effusion is present, and the sign is stated to be of great value in diagnosing between pleurisy and pneumonia. Roch and Dufour (*La Semaine Médicale*, October 21st, 1908) find that, according to many Italian observers, Grocco's triangle is always to be found in cases of pleural effusion, and that it is of real diagnostic value. In Germany, Rauchfuss is a very strong advocate of the value of Grocco's sign. He has found it to be present in 77 cases of pleurisy in children, and in every case in which a free effusion reached the level of the eighth dorsal vertebra. He does not find, however, that the sign varies according to the position of the patient. At Escherich's clinic Hamburger has frequently found in children a zone of paravertebral dullness on the side opposite to a pleural effusion, which, however, he has found to take the form of a longitudinal band rather than that of a triangle: this sign he finds, however, occurs in all conditions in which there occurs a hepatization or extensive infiltration of the lung, and he does not think it of diagnostic importance. Pollak draws similar conclusions. In France Cassatè is convinced of the value of this sign, and according to him it occurs in all large pleural effusions, and that when found it is sufficient evidence for the diagnosis of an effusion. Darier and Bernard hold much less positive views. In England and America, Ewart, Thayer, etc., conclude that the sign of Grocco is of considerable value in the diagnosis of pleurisy. The paravertebral triangle of dullness has, however, been found in cases of disease beneath the diaphragm: thus Ewart found it in a case of pyuria with lumbar abscess, Beall in sulphuric abscess, and Smythies found it in a woman suffering with an ovarian tumour. When one seeks for an explanation as to the cause of Grocco's sign, the opinions of different investigators are at still more variance. Some think that the fluid arrests the vibrations on the spine and side, and hence a diminution of resonance occurs on the side opposite to the effusion; for this view there is no evidence. Others think the mediastinum is pushed over to the healthy side by the effusion, thus causing compression of the healthy lung. Others think that the posterior pleural cul-de-sac distended with fluid passes across the middle line, pushing before it the posterior mediastinal contents and encroaching on the healthy side. The marked prominence of the vertebral bodies renders the two latter theories extremely unlikely explanations. The experience of the authors of this paper is as follows: They have found the paravertebral dullness present in some cases of pleural effusion; this area of dullness was, however, more in the form of a longitudinal band than in the form of the triangle as described by Grocco. They found that this band did not alter appreciably according to the position assumed by the patient. They found it present in cases of pneumonia and after evacuation of a pleural effusion by aspiration. Further, they have convinced themselves that in healthy adults there is present on each side an area of relative dullness corresponding to the lower and inner borders of the lungs. These two areas of dullness come together at the line of vertebral spines and at the level of the fourth and fifth dorsal vertebrae form a band 6 to 7 cm. in breadth; this band of dullness, traced downwards, enlarges until it merges into the lumbar dullness at the level of the tenth dorsal vertebra; it measures approximately 12 cm. across. The dullness, the authors consider, is due to the presence of the vertebral column and the large muscles which fill up the costo-vertebral gutters and which,

increasing in thickness as they do from above downwards, give rise to that gradual impairment of percussion note as one proceeds from above downwards in these regions. In none of the cases of pleural effusion investigated by the authors have they found the extent or the degree of this paravertebral dullness to be greater than in persons free from effusion. The conclusions drawn by the authors are that in the adult the triangle of paravertebral dullness is not pathognomonic of pleurisy, and it is of no help in the diagnosis of lung affections from pleurisy.

90. Tricuspid Regurgitation.

THE correct diagnosis of insufficiency of the tricuspid valve is extremely difficult, and our knowledge of the attending conditions is limited. The textbooks give but little information on the subject, and it has to be admitted that comparatively little important work has been carried out in connexion with it. D. von Tabora (*Deut. med. Woch.*, November 26th, 1908) deals with this subject and presents some useful information. As compared with endocardial affections of the valve, the functional or relative disease of the valve is very common. The latter is produced by a dilatation of the right ventricle. It is, however, not possible to diagnose *intra vitam* between organic and functional tricuspid regurgitation. It is stated that the symptoms of tricuspid regurgitation are those of extreme insufficiency of the heart. The author cannot accept this, although he realizes that since functional disease of the tricuspid orifice is a sign of loss of compensation in cases of mitral disease, the circulation, taken as a whole, is disturbed. The possibility of tricuspid regurgitation being the first sign of cardiac weakness has not been recognized until quite recently. In examining a series of cases of anaemias of various origins no auricular venous pulse could be recorded. However, he recites the history of a case in which tricuspid insufficiency followed primary weakening of the right ventricle. The curve of the jugular vein showed a ventricular pulse, while the arrhythmia was seen to correspond to what is known as *pulsus irregularis perpetuus*. The symptoms usually ascribed to tricuspid regurgitation are: extension of the cardiac dullness to the right, pulsation to the right of the sternum, systolic murmur, soft second pulmonary sound, systolic venous and liver pulse, severe signs of failure of the heart (ascites, oedema, etc.). On examining his cases he found that while the extension of the cardiac dullness to the right was present in all cases, it was not extreme in more than half the total number. Pulsation to the right of the sternum is rare, and is only met with in extreme cases. In none of his cases could he definitely localize a systolic murmur to the tricuspid orifice. As a rule, when such was present, it was quite as intense or more so at the apex or at the pulmonary orifice. In a considerable number of cases of undoubted tricuspid regurgitation he did not hear any systolic murmur at all. The same experience was made with regard to the supposed softening of the second sound at the pulmonary area. He does not believe that it has anything to do with tricuspid regurgitation, and maintains that the majority of cases do not show this sign. The only symptom which remains over is the systolic venous and liver pulse. This is called positive or ventricular, and corresponds to the contraction of the ventricle in point of time. Inspection and palpation are not capable of determining such a pulsation. A suggestion has been made that if the jugular vein be compressed digitally and observation be made whether the central portion of the vein fills again or not, regurgitation of the tricuspid valve might be diagnosed. Von Tabora, however, considers that this is extremely unreliable. In many cases the venous pulse is not visible, and it is therefore essential to record it graphically. He discusses the various points in connexion with the type of curve obtained from cases of this kind, and appends some illustrative curves. Marked tricuspid regurgitation, even if of functional origin, rarely clears up completely. It is, however, possible for the symptoms to disappear, and the patients may then pass months or years without any subjective signs pointing to heart disease. In a few isolated cases von Tabora believes that tricuspid regurgitation occurs as the first sign of cardiac failure, but this must be regarded as being very rare.

SURGERY.

91. Treatment of Perityphlitis.

KLAUBER (*Med. Klin.*, July 12th, 1908) advises immediate, and, wherever possible, radical operation in every stage of appendicitis. He claims that by this means he has reduced the mortality of the cases in his hands from 39 per cent. in 1905 to 12 per cent. in 1905, and 8 per cent. in 1907. During 1902 to 1905 he employed the expectant treatment, with the following results. All those tabulated are late cases—that is, operated upon over forty-eight hours after the commencement of the illness.

Abscess incision	26	Two deaths from fistula and pleurisy respectively.
Extraperitoneal appendectomy	13	No deaths.
Laparotomies	21	Twelve deaths—57 per cent.
Total	60	Fourteen deaths—23.3 per cent.

From August, 1905, to March, 1908, all late cases were operated upon at once, no case being refused operation, with the following results:

Abscess incision	11	No deaths.
Laparotomies	43	Two deaths—5 per cent.
Total	51	Two deaths—3.9 per cent.

Klauber bases his opinion upon the following considerations: The clinical division into early, intermediate, and late stages was found in numberless cases not to correspond to actual anatomical conditions. It is never possible to tell at the commencement of a case whether it will run a mild or severe course. The mortality of cases operated upon in early and late stages is not comparable, because in the latter a waiting policy has been employed, and operation has been undertaken either experimentally after an abscess has formed, when results have been excellent, or intraperitoneally after peritonitis has occurred, when the mortality has been 50 to 60 per cent. It is to avoid this mortality that Klauber advises early operation in all cases. Those cases which would otherwise be opened extraperitoneally are not endangered by early operation, as is shown by Klauber's two deaths. The one died from an abscess of the liver present at the time of the operation, the other from intestinal paralysis existent four days before operation, while at the autopsy the peritoneal purulent exudation was found to have disappeared. On the other hand, a waiting policy may lead to disastrous results. A perityphlitic movable tumour may be felt in the abdomen, causing no severe general symptoms, but at the operation a mass of omentum containing the gangrenous appendix and a sanious abscess may be found, the whole mass freely movable. Expectant treatment of such a case would lead to intraperitoneal bursting of the abscess and general peritonitis; or a second abscess may be found in the pelvis as well as the perityphlitic abscess, well marked off, and with healthy surroundings. The appendix is always removed, because the author finds that only in this way can the various burrowing abscesses be drained, and its removal means also the removal of the source of infection. This has not been found difficult. The pelvis should always be examined, even in cases of apparently well-circumscribed abscesses, as collections of fluid may be found here, and a drain inserted towards the pelvis may guide, on the second or third day, the exit of a quantity of pus. A large collection of exudation in the left half of the abdomen necessitates a counter opening on the left side and drainage. Klauber disapproves of irrigating the abdomen, because (1) in bad cases it is useless; (2) favourable cases do as well without; and (3) in certain other cases—for example, perforation—it was found to cause multiple abscesses, whereas in similar cases, where irrigation was not employed, these did not occur. Nature's method of irrigation is assisted by the administration of fluid per mouth and rectum. Every hollow of the abdomen where fluid exudate collects should be drained. The author's unfavourable results are ascribed to virulence of infection or to intestinal paralysis which occurred mostly after previous opium treatment. In none of the author's last 56 cases was it necessary to perform a further operation in order to open a peritoneal abscess, to drain Douglas's pouch, etc. Whenever intestinal contents appeared on the dressings, as was often the case, indicating a fistula, all plugging was removed, and the wound cavity was kept clean by irrigation without pressure. All cases healed without requiring operation.

92. Extravesical Suprapubic Prostatectomy.

STOCKUM (*Zentralbl. für Chir.*, No. 3, 1909) holds that though the suprapubic is preferable to the perineal method of prostatectomy, the former is still to be re-

garded as a dangerous operation, and that it is therefore advisable to make effort to improve its technique and to diminish as much as possible its undoubted risks. The following description is given as a modification of the high operation, devised by the author and practised with success in two cases of enlarged prostate. In this procedure, which is named "extravesical suprapubic prostatectomy," the enlarged gland is first attacked at its urethral portion, and the only opening made in the upper part of the bladder is a small puncture which serves for the introduction into the vesical cavity of a drainage tube. The usual median incision having been made above the pubic symphysis and the recti muscles separated, the operator's finger is passed downwards in front of the bladder until it reaches the vesical end of the urethra and the enlarged prostate. In order to obtain good access to the gland the fatty tissue behind the symphysis, together with the fold of peritoneum, should be carefully stripped away from the bladder, but not further than is absolutely necessary. The lateral paravesical connective tissue should be left undisturbed. Over the upper part of the exposed prostate, a little to one side of the middle line, a short vertical incision is made through the capsule into the glandular tissue. Through this opening the surgeon introduces at first one finger and afterwards two fingers and enucleates the gland, guidance being afforded by a catheter previously introduced along the urethra into the bladder. During the enucleation the prostate is pressed upwards and forwards by an assistant's finger in the rectum. After the removal of the enlarged gland the wound is closely packed with gauze with the object of preventing secondary hæmorrhage; after the introduction of a drainage tube into the bladder the upper portion of the abdominal wound is closed by sutures. In one of the author's cases the gauze packing and the vesical drainage tube were removed on the fifth day, and for the next seven days the bladder was drained by a urethral catheter.

OBSTETRICS.

Contracted Pelvis.

93.

AT the International Congress for Gynecology held in Geneva in 1896, the frequency of contraction of the pelvis in the various countries was discussed, but inasmuch as the data obtainable were insufficient, the subject was postponed for a future occasion. A. Hegar now takes up the same theme and deals with the whole problem briefly in the *Muench. med. Woch.* of August 25th, 1908. Collecting his facts from the work of others, he finds that in Austria-Hungary 8.08 per cent. of pelvis which were measured proved to be contracted. Dohrn found the percentage in Germany to be between 12 and 20. Barnes found that in England 0.4 per cent. of the examined pelvis were flattened and 0.12 per cent. generally contracted. Hegar suspects that some mistake must have arisen in these measurements, as they are so much lower than those made in Germany, although he recognizes that much is done in England to guard against deformities in the way of exercise, good nutrition, etc. Ogata found that with the exception of one district, where osteomalacia and rickets are prevalent, no contracted pelvis are met with in Japan. Simpson and Stenat found that the percentage for Scotland was 6.3 to 6.9, while Glasgow gave a percentage of 10. Möller worked the material in Norway up and found that in the northern countries contracted pelvis were very uncommon. Brandt and Petersen, however, found 3.61 per cent. In Denmark it appears to be about 4 per cent. The reasons why contracted pelvis is so much less common in Norway and Sweden than in Germany is, in Hegar's opinion, not difficult to discern. The women in the two former countries are better cared for, they work healthily in such callings as agriculture, forestry, shipping, etc., and not in the industries. Alcoholism is being effectually battled against, and, last but not least, the women nurse their own babies. Developmental disturbances play a large part in the etiology of this deformity. The beginnings may be laid down in fetal life, or some noxious influence may act early in independent life. In infantism it is not only the pelvis which shows the disturbance of development. Freund and Mendelsohn have shown that infantile types of the pelvis are frequently associated with stenosis of the upper aperture of the thorax. The noxious influences which may contribute to this end are largely to be neutralized by breast feeding in infancy, by proper feeding, good hygienic conditions in the home, sufficient exercise in fresh air, and the avoidance of taking part at an early age in the so-called social pleasures, for example, theatre, concert, and ball attendance, during childhood. Next, the prevention of certain diseases must be regarded as preventive measures

against the development of contracted pelvis. Of these, chronic infections, and especially tuberculosis, are the most important. Cretinism is a cause of contracted pelvis. Added to infantilism and cretinism, rickets must be mentioned as a cause of this condition. The recognition of the etiology of contracted pelvis must serve as a basis of preventive measures. Hegar points out that a study of this problem, if carried out properly, will give the index for preventive treatment, and his remarks tend to give a guidance for such a treatment.

94. Pyelitis in Pregnancy: Irrigation.

STOECKEL (*Zeit. f. gynäk. Urologie*, vol. i, part i, 1908) writes on the diagnosis and treatment of this complication of pregnancy, having already demonstrated his views and practice at the eightieth meeting of the Deutsche Naturforscher und Aerzte at Cologne in September. He observes that the disease of the kidney is actually caused by the pregnancy, that retention of urine in the ureters plays a prominent part in the production of this complication, that the urine in pyelitis contains the *Bacillus coli* either alone or with other germs, and that pyelitis is not only most frequent but also most severe when the right kidney is affected. Diagnosis, Stoeckel insists, is not easy. Pyelitis is very often overlooked when cystitis is present, and when the bladder remains healthy the clinical symptoms simulate inflammatory disorders of the gall bladder, vermiform appendix, and uterine appendages. Cystoscopy with double catheterism of the ureters can alone make diagnosis sure. As for treatment, induction of abortion is to be rejected, and nephrotomy is only to be practised when there is evidence of true pyonephrosis. The right treatment, eminently surgical, is irrigation of the renal pelvis with antiseptic solutions, such as collargol. Five women have already been successfully treated by this method, the pain and fever disappearing and the pregnancy remaining uninterrupted. All the children were saved and reared. Stoeckel reports three cases, and writes the technique of his method, adding an illustration.

GYNAECOLOGY.

95. Placental Syphilis

W. O. PAULI (*Johns Hopkins Bull.*, November, 1908) says that the fact that various authors have reported the finding of the *Spirochaeta pallida* in the placenta of syphilitic infants, while other observers have failed to find the organisms in the placenta, though they were present in the majority of instances in the fetal organs, gave rise to this investigation. The diagnosis of syphilis of the placenta was based on the presence of the following conditions. On gross examination: (1) An increase in the size and weight of the placenta in relation to that of the child, the increase being from 1.6 (the normal ratio) to 1.4 or even more; (2) a pale pink coloration and greasy feel of the maternal surface of the placenta; (3) an abnormal width and depth of the intervillous spaces. On microscopic examination: (1) A thickening and clubbing of the ends of the finer branches of the villi; (2) absence of blood vessels in the finer branches of the villi and their partial obliteration from endarteritis in the rest; (3) an abnormal density and hypernucleation of the stroma. During the year 1907-8, 825 placenta were examined, and of these 25 were pronounced syphilitic, after microscopic examination of sections, by Professor J. W. Williams. An autopsy was made on the infants in 16 out of these 25 cases. In 14 cases the diagnosis of syphilis was made on anatomical grounds, and in 11 of the 16 was established by the finding of the *Spirochaeta pallida* in the fetal organs. Twenty-four of the 25 placenta were examined for the spirochaete (the tissue in one case being lost), but in no case was it found even after careful and repeated search. Levaditi's method of staining was used in every case. The grounds for making an anatomical diagnosis of syphilis in the fetus were (1) an increase in the size and weight of the liver and spleen; (2) the presence of pneumonia alba; and (3) the presence of definite osteochondritis at the epiphyseal line of long bones. In the literature the author has been able to find 120 cases of examination of syphilitic placenta for the *Spirochaeta pallida*, with positive results in only 16 of these. He concludes: (1) That the spirochaete is rarely found in syphilitic placenta; (2) that the anatomical changes observed in the placenta are the result of toxins produced by the spirochaetes in the fetal organs; (3) that the placenta is not the nidus of infection. This comparative immunity of the placenta, particularly of the maternal part, may be due to its close connexion with the maternal blood and its contained antibodies or immune substances.

THERAPEUTICS.

96. Treatment of Pernicious Anaemia.

G. KLEMPERER records the results of some experiments made on patients suffering from pernicious anaemia (*Berl. klin. Woch.*, December 28th, 1908). The usual treatment has proved itself incapable of preventing recurrences which sooner or later end with death. Cases, however, are recorded which have lasted for as long as thirteen years, showing numerous recurrences. The characteristics of the disease include the marked diminution of red blood corpuscles, with an increased haemoglobin index, the presence of nucleated red cells, including megaloblasts, while the white corpuscles are not increased in number, and may be diminished. His therapeutic experiments are divided into two chapters. The first were conducted with cholesterin. That substance occurs not only in bile, but also in practically every animal and vegetable cell. It has been shown that cholesterin becomes visible when the cell dies, and when destruction of body cells takes place, cholesterin enters the blood freely, and a sort of lipid-æmia is produced. When red blood cells are destroyed in large quantities, the bile becomes richer in cholesterin, and the same substance appears freely in the faeces. Further, it has been shown that the haemolytic action of a substance called saponin can be prevented by cholesterin. Cobra poison is also neutralized by this substance. It has been employed in the treatment of the anaemia following cobra poison lecithide intoxication with good results by Morgenroth. The same author has suggested that it might be of use in pernicious anaemia. If cholesterin is capable of acting beneficially in this disease, it would be clear that pernicious anaemia is a haemolysis. This, however, is not recognized up to the present. No free haemoglobin has ever been found in the serum of the patients, nor has haemoglobinuria been noticed, although the presence of urobilin may be regarded as a sign that red blood cells have been disintegrated and the contents set free. Klemperer further states that the cholesterin content of the serum of pernicious anaemia patients has been determined in a few cases and is not diminished. Notwithstanding these objections, he employed cholesterin as a form of treatment. The difficulty of applying cholesterin in a 5 per cent. solution in oil was found to be considerable, as the patients did not tolerate the oil well and could scarcely be induced to swallow it. Previous experiments, however, had taught him that the ingestion of milk, cream and butter in large quantities increased the quantity of cholesterin considerably in the serum. Butter and other milk products contain considerable amounts of cholesterin. One litre of cream and 200 grams of butter correspond to 2.1 grams of cholesterin. By boiling these with gelatine and sugar, and in other ways, it is possible to prepare this quantity of cream and butter so that the patients will take it in every day. Some patients only took half this quantity, but even this quantity proved itself capable of exercising a marked effect on the general nutrition. In all, 8 cases were so treated. They were placed on a mixed diet with as much milk, cream, and butter as they could take. In order to enable them to digest the large quantity of fat more easily, they were given small doses of brandy and a powder consisting of calcium carbonate and calcium phosphate. Only one patient was treated by means of the cholesterin alone, while the other 7 patients, whose illness was too severe to chance it, were given arsenic as well. The first patient put on 6 lb. in weight, and his red blood cells increased from 2,720,000 to 2,930,000 per cub. mm. His general condition was materially improved. In two of the other cases the treatment was begun with arsenic (atoxyl), and as soon as some improvement manifested itself the cream and butter treatment was pushed. The weight improved under this, and the symptoms of the disease also diminished. The results, however, were not so brilliant as would justify him to be satisfied with them, and for this reason Klemperer sought for a better form of treatment. The possibility that pernicious anaemia may be an infection, and the occurrence of severe forms of anaemia in kala-azar, suggested that the more modern forms of arsenic might be tried. He therefore applied arsacetin, which Ehrlich has recently introduced for other forms of disease—namely, for the protozoal infections. He injected 0.1 gram of this substance subcutaneously in a 10 per cent. solution, and worked the dose up to 0.6, without any ill effects presenting themselves. The effect on the blood was very marked. The number of red blood corpuscles in the 6 cases in which arsacetin was employed increased very considerably. The improvement only continues up to a certain limit, and he has found that it is then useless to continue the treatment. If a recurrence sets in later the

treatment can again be taken up. He does not claim that either of these two forms of treatment can cure pernicious anaemia: but both have done good in all his cases, and he considers that this, at all events, is one step onwards.

97.

Sabromin.

EULENBURG (*Mediz. Klinik*, November 8th, 1908) has tried sabromin in 14 cases, sufficiently long to judge of its efficacy, especially as compared with other bromine preparations. Six of these were cases of epilepsy, which had all been treated for a long time previously with other bromine preparations, more or less adequately. Bromine, given in the form of sabromin, gave equal if not better results than twice the amount given in the form of alkaline bromides. A striking success was obtained in the case of a lad of 18 who had had seven severe fits during the previous year, the two last six weeks and ten days respectively before the commencement of the treatment. Four tablets (2 grams) were given daily, and no further fit occurred, so that five months later the dose was reduced to three tablets, and later to two. No unpleasant side-effects occurred, and the psychical state remained unaltered. In 2 cases it was found necessary to add other bromine preparations. In several cases increase of weight (1½ to 5½ kilog.) occurred during the use of sabromin. In the other 8 cases, of chronic neuroses, sabromin was strikingly successful in 2—one a case with attacks of psychic depression, and the other an elderly lady with obstinate pruritus. In the latter case the pruritus completely disappeared after hardly a week's treatment. The drug proved very useful in 2 cases of sexual neurasthenia, but in the other cases it was less successful. The cost is M. 1.35 for twenty tablets. Sabromin contains 50 per cent. bromine, as against 67 per cent. in potassium bromide. It should always be given one hour after meals, and should be either masticated or broken up in water before taking. It is tasteless, and causes no gastro-intestinal disturbance or signs of bromism. Eulenburg only once saw a slight acne.

98.

Paraganglin in Senile Tremor.

TARABINI AND MASSAGLIA (*Gazz. degli Osped.*, December 13th, 1908), in view of the recent experimental work in relation to the parathyroid glands and their influence over various convulsive muscular attacks, have tried the effect of paraganglin (Vassale) in two cases of senile tremor. Whilst believing that senile tremor and paralysis agitans own a more or less common origin, and may, indeed, be looked upon as different degrees of a more or less similar condition, they hold that the two affections are rightly separated from a clinical point of view. They differ, for example, in origin; senile tremor always begins in a slow and subtle manner, whilst paralysis agitans sometimes begins quite suddenly, and attacks men rather than women. The tremor in paralysis agitans is at first limited to the limbs, whence it is diffused to the body at large and to the head: on the other hand, the oscillations of senile tremor affect the head, jaw, and upper limbs, and are simple in type (no twirling movements of the fingers such as one often sees in paralysis agitans), and seldom accompanied by the muscular rigidity, sleeplessness, peculiar gait, mask, etc., of the typical paralysis agitans. Both the cases were women, aged 76 and 75, and the drug was given in tabloid form. In the first case, it was noted that after about fifteen days' treatment the tremor was much diminished in intensity, and ceased for more or less long periods, and a troublesome pain in the muscles of the neck was also much relieved. No actual cure was obtained, but so much relief (far more than had ever been obtained by any of the numerous drugs previously tried) was effected that the patient, when the treatment was suspended for a short time, strongly urged its renewal. In the second case an absolute cessation of tremor occurred for a short period after the treatment was commenced, but unfortunately this proved to be only temporary, and it returned as badly as ever after a few weeks.

99.

Synthetic Suprarenin.

KRAUPA (*Mediz. Klinik*, September 6th, 1908) has tested suprarenin, prepared synthetically, with adrenalin, tonogen, and suprarenin obtained by extraction from the suprarenal capsule. Synthetic suprarenin is a solution of the chloride in physiological salt solution in the proportion 1 in 1,000, with 0.6 per cent. thymol added to preserve it. By instilling this in one eye of an individual and one of the other substances in the other eye, he found on comparison that its action was precisely similar in every respect, both in normal and in inflamed eyes. The same held good for subconjunctival injections. On boiling the solution for three minutes, it remained unchanged, and even when boiled for half an hour, no lessened action could be

observed. When allowed to remain exposed to the air for eight days the solution became slightly coloured, but retained its action on the vessels completely. Kraupa concludes that synthetic suprarenin is in every respect equal to the other suprarenal preparations, and it is, moreover, cheaper.

PATHOLOGY.**100. The Morphology and Biology of Malignant Tumours.**

C. LEWIN is of opinion that neither Cohnheim's nor Ribbert's theories as to the nature of cancer can be accepted (*Berl. klin. Woch.*, December 16th, 1907). The former believed that cancer was caused by the growth of widely distributed embryonic residues, but he failed to produce malignant growths by transplanting embryonic tissue into animal organisms. The latter thought that cancer was brought about by a disturbance of the arrangement which keeps the cells of the organism in regular connexion with one another. This disturbance was supposed to be called forth by a primary overgrowth of connective tissue, which caused the expulsion of the cells from the organic connex. He is further convinced that all the attempts to produce cancerous growths by chemical or mechanical stimuli have failed, although he owns that Fischer has succeeded in producing an atypical overgrowth by means of scarlet red oil. The workers who pinned their faith on a parasitic origin of cancer have also failed to reproduce anything at all similar to a malignant growth artificially. The work which certain experimenters have been carrying out recently, however, has thrown some light on the dark problem. Ehrlich, Apolant, Bashford, Borrel, Haaland, and Michaelis have worked with transplantable tumours of the mouse. Striker has utilized lymph-sarcoma of the dog. At first some doubt was expressed whether the mouse tumours were in reality real cancerous tumours. It is now a matter of indifference whether these tumours have an endothelial or epithelial origin, since their malignity has been amply demonstrated. Apolant, however, has conclusively shown that the mouse tumours were real epithelial growths which almost always had their origin from the mamma. The slight infiltration of these tumours was accounted for by the fact that they grew in very loose tissue, the subcutaneous tissue. Haaland has further shown that a large percentage of the transplanted tumours gave rise to metastases in the lungs. He owns, nevertheless, that there are many points in which these tumours differ from cancer of human beings. In order to meet this objection he now brings forward an account of the behaviour of a mammary carcinoma of the rat, which he thinks is more analogous to that of the human subject than any of the tumours of mice or rats which have yet been described. This tumour is now in its thirteenth generation. Its chief characteristic is that of forming metastases very freely. In almost every inoculation generation it produced metastases in the lungs, liver, spleen, and in contrast to mouse carcinoma it was transplantable on the peritoneum, where it produced ascites and general cancerous infiltration of the peritoneum. The rats died of cachexia, while the tumours infiltrated solid tissues or internal organs. He reproduces the microscopical appearances of the original tumour, which possesses the characters of a primary pure adenocarcinoma of the mamma. In the third generation, however, he found that the type had suddenly become modified. Here he found the adenocarcinomatous structure in places, while the mass of the tumour which developed from a subcutaneous inoculation was that of a typical canceroid. Since this tumour was seen he has succeeded in producing tumours which were either mixed tumours or either pure adenocarcinoma or pure canceroid tumours. From the fourth generation onward the peritoneal inoculation led to solid carcinomatous growths without any keratinization and without prickle cells, while keratinization was always well marked after subcutaneous inoculation after the seventh generation. He denies the possibility that the primary tumour was in reality a mixed tumour. This he bases on a number of contentions. In the third series of the fifth generation he found that the connective tissue began to overgrow, and this overgrowth consisted chiefly of spindle cells. On inoculating these outgrowths further, he found that he obtained tumours which were indistinguishable from Ehrlich's mixed-celled sarcoma, some of which showed a preponderance of spindle and some of round cells. He succeeded in raising the virulence of these tumours until he obtained inoculation tumours in 100 per cent. of the attempts. He concludes with some critical remarks on the problem of inherited and acquired immunity towards these artificially-produced tumours.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

101. *Achylia Gastrica in Childhood.*

It is usually said that achylia gastrica becomes increasingly frequent with age. According to Branner it is seldom, if ever, found before puberty. A. Hecht (*Wien. klin. Woch.*, November 5th, 1908) has seen the following case. A girl, aged 9, was said to have been healthy till the age of 4, when she suffered from abdominal pain and frequency of micturition. She ate well, but lost flesh, and was backward developmentally. On admission to hospital there was extreme emaciation with dry scaldiness of the skin. There were slight dyspnoea and dullness, and harsh respiration anteriorly at the right apex. The liver and spleen were of normal size. The appetite was good. Two to five putraceous or liquid, fetid, clay-coloured stools were passed daily, and the diarrhoea persisted as long as the child was under observation (from June 22nd to July 17th). The urine and temperature were normal. Von Pirquet's tuberculin vaccination gave at first a negative, but later a positive, result. An injection of tuberculin was followed only by a local needle-track reaction. A blood count gave no important information. The child was, on June 24th, placed on A. Schmidt's No. 2 test diet, consisting of $\frac{1}{2}$ litre milk-cocoa and a piece of toast (*Zwieback*) for breakfast; beef-tea with an egg during the morning; oat-water with milk and half the yolk of an egg, 5 dgm. of rather overdone minced meat, 5 dgm. of mashed potatoes with butter, and a piece of *Zwieback* for dinner; for tea the same as for breakfast; and macilaginous oat-water with half the yolk of an egg for supper. On June 26th the stools were putraceous, frothy, of a bright greyish-yellow colour, and strongly alkaline—possibly from the admixture of ammoniacal urine. The shreds of mucus in the faeces, when stained, appeared microscopically as thick red filaments, and contained but few cellular elements. The presence of numerous muscular fibres with intact striation and no signs of digestion, the paucity of connective tissue, the absence of starch, and the presence in the faeces of small white granules, which consisted almost entirely of needles of fatty acids, with exceedingly few droplets of fat, all indicated serious disturbance in the digestion of meat, with a well-maintained fat-splitting function. Repeated examination of the gastric contents after test meals showed the constant absence of rennet and HCl. scarcely any fat was split up in the stomach, and pepsine was greatly deficient, and at times entirely absent. On one occasion trypsin could not be found in the faeces, but this was of doubtful significance. The patient was probably tuberculous, but the chronic diarrhoea was evidently due to gastric achylia. The writer believes that if the gastric functions were investigated in every case of chronic diarrhoea achylia gastrica would be found not infrequently.

102. *Pigment Disappearances in Skin and Hair.*

SCHIEIN (*Pester Mediz.-Chirurg. Presse*, October 25th, 1908) considers that pigment atrophy in a large number of cases, if not in all, follows upon previous excessive production of pigment. For example, grey hairs appear earliest from follicles whose previous hairs have been richest in pigment, or longest, or have grown most rapidly, and thus been replaced more often by successive hair-generations (the life-length of a hair is from two to four years)—that is, where much pigment has been previously formed and consumed. Schein quotes a case where the hairs had been previously noticeable for depth of pigmentation. That long hairs whiten sooner than short ones is shown by the fact that the hair of the head and beard become grey before that of the rest of the body, the hair on the shoulders, breast, and pubes before that of the eyebrows. The beard whitens soonest at that part of the chin where, at puberty, the first hairs grow, at which place they also grow to be longest. Fohl found that in senile baldness the individual hair generations were shorter lived, and it may be also that senile grey hairs follow on the excessive pigment production caused by an increased number of hair generations. In a case of trichiasis where epilation was frequently performed Schein noticed after a time that the new eyelashes were white. After the application of

the Roentgen rays darker hairs grow first, and these are followed by lighter ones. Vitiligo is very frequent in negroes, especially at parts rich in pigment—for example, the penis, scrotum, or where the skin is exposed to the rays of the sun. The author finds his principle applicable in the explanation of leucoderma syphilitica, and of the pallor surrounding syphilitic papules. Jadassohn used Finsen rays in a case of vitiligo and found that under their influence excessive pigmentation was replaced by pigment atrophy. That the skin from which grey hairs spring is normally pigmented is explained by the much smaller demand on pigment made by the skin than is made by hairs. Schein concludes: (1) That pigment production in man is limited; it differs in different races and individuals—for example, it is much greater in negroes than in Caucasians, in dark people than in light. Different organs and tissues possess different powers of production. (2) The upper limit of pigment production is sooner reached in dark than in light people. (3) When this limit has been reached further stimulation leads to atrophy, which will account for cases of sudden bleaching of hair. (4) This stimulation may be the same which previously caused the excessive pigmentation.

103. *Cutaneous Hyperalgesia.*

ELSBURG AND NEUBOF (*Amer. Journ. Med. Sci.*, November, 1908), from the examination of a large number of cases of abdominal affections, verify the findings of Henry Head as to the diagnostic value of cutaneous hyperalgesia (Head's zones) in abdominal disease. The pin method of examination was adopted, and found to be satisfactory for practical purposes, a sharp pin being held between the thumb and index finger of the right hand and drawn slowly along the surface of the skin, while the nail of the index finger rests upon the patient's skin and presses equally along the area examined. The patient is told to say "now" as soon as the pinstroke becomes painful, and care must be taken that the pressure of the pin point remains constant, especially as it passes over the groin or costal margin. By this means zones can be mapped out, and the procedure repeated a second time, both the patient and the operator keeping their eyes away from the pin, so as to eliminate as far as possible the personal equation in the examination. The zones may appear very early in the course of visceral affections, and they usually persist throughout the course of the disease, disappearing promptly with the relief of the lesion. Occasionally, however, zones may disappear suddenly, with a persistence or sudden increase in the general symptoms; and when such is the case, it may be of grave significance, betokening in mild cases of appendicitis the development of severe symptoms, and rendering operative interference imperative. Zones may be absent, and while such absence does not mean that there is no disease of the organ suspected, the presence of a zone implies an undoubted lesion. For purposes of diagnosis a Head zone must not be the only factor relied upon, though in the absence of all other localizing signs such a zone may indicate the organ affected. As an aid to diagnosis, and used in conjunction with other symptoms, a zone may be of value to substantiate conclusions arrived at from a general consideration of all the signs and symptoms. In patients with marked abdominal distension and rigidity the presence of a characteristic zone has greatly helped in the differential diagnosis between disease of the gall bladder and appendix, gall bladder and kidney, and between disease of the appendix and uterine appendages. In the early stages of abdominal disease such zones of hyperalgesia may be of value in helping to form an early diagnosis. The degree of cutaneous hyperalgesia has no constant relation to the severity of the pain or gravity of the mischief attending the lesion. The presence of several zones may indicate a combined lesion of several adjoining viscera, but in such cases the possibility of the cutaneous hyperalgesia being due to a lesion of the cord must be borne in mind. Though they may vary somewhat in extent and outline, these zones have a characteristic location, and present very constant and definite areas of hyperalgesia, but the presence of such a characteristic zone, while being evidence of an affection of the corresponding abdominal viscus, need not of necessity point to the affection which is causing the symptoms in any given case.

SURGERY.

103. Rubber Gloves and their Substitutes.

G. BECKER (*Deut. med. Woch.*, December 10th, 1908) says that Unna recommended, in 1885, covering the hands with a layer of soap, in order to cut off the bacteria present in the deeper parts of the epidermis, when it was required to disinfect the hands. Mikulicz suggested using thread gloves, Perthes suggested using silk stockinette gloves, and Wollfer suggested leather gloves; but all these methods proved to be insufficient for the purpose. Friedrich found a solution of the difficulty in 1898 in the shape of rubber gloves. It has been shown that these can be sterilized, and provided that no cuts or tears are present, the field of operation may be kept free from bacteria from the hands of the operator by their means. The sterilization may be carried out by means of steam or by boiling. Steam has the advantage that the gloves can be used in a dry condition. The author shows that the fears which have been expressed that the steam may not penetrate into the interior of the glove is not well founded, and he has found experimentally that gloves sterilized by steam are sterile inside and outside. Various devices have been suggested to guarantee the full action of the steam, such as stuffing the fingers with wool or other material, hanging the gloves up by the fingers, or putting them on nickel skeletons, but all of these devices are unnecessary. There is, however, no doubt that sterilization does attack the rubber, and after two applications of steam the gloves tear very easily. Boiling is better tolerated, but this has the disadvantage that after the process the gloves become sacklike and no longer fit the fingers. It is uncomfortable to wear gloves which have been boiled. Gloves are therefore costly as a means of protecting against infection by the hands. An advance has been made in this direction by the introduction of a method of disinfecting the surface of the gloves by washing in water and soap for three minutes, and then disinfecting for two minutes in corrosive sublimate solution. A further disadvantage of gloves is found in the fact that they can be cut by instruments, and then the danger of wound infection is greater than if no gloves had been worn at all. It was to overcome these disadvantages that certain substitutes for rubber gloves have been introduced. The author mentions two of these, Klapp's *chirostoter* and Wederhake's *dermagummit*. The first named is a solution of a waxy and balsamic body in carbon tetrachloride, which is sprayed on the hands and rubbed until dry. It is supposed to fix the bacteria in the deeper layers of the epidermis as paraffin fixes the specimen in embedding. Becker has experimented with soiled hands and *chirostoter*, and has found that relative and not absolute sterility of the surface of the skin could be obtained by this means. He mentions that the space beneath the nail is not completely shut off, and that reliable results can therefore not be expected. *Dermagummit* is prepared by Dr. Degen and Kuth's factory in Düren (Rhine), and is a patented solution of gum elastic vulcanized by iodine. It is sold in sterile bottles, and should be applied to the hands after these have been disinfected in the usual manner and dried with a sterile towel. The rubber solution is rubbed on the hands until a thin layer covers every part, and is then allowed to dry. It is advisable to powder the surface with sterile talc or caolin to prevent the hands from remaining sticky. Each application to the hands costs from 4 to 6 pfennigs (1 pfennig is nearly one-hundredth of a shilling), but the cost of removing the layer must be added to this. The removal can be done with carbon tetrachloride, ether, or benzine. First Becker tested whether chemical substances like the ferrocyanide of potassium could pass through the layer, and he found that this was not the case. Next he tested the efficacy of the sterilization process. Hands were infected with *prodigious* cultures and then covered with *dermagummit*. On rubbing sterile potato on the hands some remained sterile, some showed growth, but none showed as free growth as did the control potatoes rubbed on the hands before the *dermagummit* was applied. Passing silk behind the nails of the ordinary hands after treatment with *dermagummit* removed micro-organisms which grew well on agar. Probably the drawing of the silk through out into the rubber coating. Although he admits that when the hands are disinfected before the application of *dermagummit* the bacteria are very largely diminished, he does not consider that we have any right to rely on the absolute sterility of hands treated with this material. He claims that sterile rubber gloves are more reliable, and even when soiled these can be rendered absolutely sterile

in five minutes with water, soap, and perchloride of mercury: 8 per cent. formaldehyde or formogen achieves the same effect in one minute.

105. Nerve Suture.

ALFRED S. TAYLOR (*Amer. Journ. of Orthopaedic Surgery*, November, 1908) says that, concerning the regeneration of the distal portion of a divided peripheral motor nerve, there are two views. The "Peripheralists" assert that it undergoes a process of regeneration from the neurilemma cells, independently of the proximal stump and the central system. This stops short of the return of function, which comes only after the reunion of the distal segment with the central system. The "Centralists" maintain that regeneration comes only as a result of the down-growth of central axis cylinders. Whichever of these theories is correct, the fact remains that even after twenty-nine years a return of voluntary control over paralysed muscles has followed the operation of nerve suture. Of first importance is the condition of the paralysed muscles, the natural tendency of which is to undergo fibrous degeneration. The rapidity with which this change develops varies very greatly. In every case the muscle condition must be tested by careful electrical test. Neglect to prevent the occurrence of deformities in paralysed limbs results in the occurrence of contractions of muscles and ligaments and maldevelopments of bones, and offers mechanical obstacles to movements which makes it impossible for even fully regenerated nerves to restore normal mobility to the damaged area. The paper is illustrated by a plate showing the various types of suture—namely, end-to-end, nerve bridging, nerve crossing or transfer, and lateral implantation, which includes a variety of procedures. The simple implantation of the paralysed nerve into a longitudinal slit in the sound nerve gives very satisfactory return of motor power, causes the minimum of disturbance in the muscle field of the sound nerve, and it should be the method of preference. The release of a nerve from constriction which has caused more or less complete peripheral degeneration has a wide field of usefulness in post-traumatic conditions. Nerve dissociation is practically an intraneural neurolysis in which a nerve trunk is separated into its several bundles to relieve them from the constriction due to increased connective tissue. The first evidences of nerve regeneration appear in improved sensory and trophic conditions. These are very variable in the time of their onset, but they are usually well advanced by the end of three months. Voluntary motion, except in a few unexplainable instances, never returns sooner than three months after operation, and often only after six to fifteen months have elapsed. After voluntary motion begins to return, progress is slow, but continues for several years, and depends upon good after-treatment, and especially upon the interest and co-operation of the patient. The paper contains illustrative groups of cases.

OBSTETRICS.

106. Pernicious Vomiting of Pregnancy.

No satisfactory explanation of the pathology of pernicious vomiting of pregnancy has hitherto been given, and probably the pathology is not always identical. Dufour and Cottenot (*Revue Neurologique*, December 30th, 1908) look to the nervous system to explain the association of gastric disorder and uterine disturbance in pregnancy. They are not dogmatic, but bring forward two cases to show that vomiting of pregnancy, at any rate of the intractable type, may be due to tabes dorsalis. One case only is reported in detail. It is that of a woman in her third pregnancy admitted into hospital in the fourth month for intractable vomiting causing much loss of weight. In her first pregnancy vomiting had lasted from the fifteenth day after the last period preceding conception until the end of pregnancy. In her second pregnancy it lasted from the second month to the end. On examination the following evidence of nervous disease was obtained: The right leg had superficial scars which had been present from infancy; cutaneous sensibility in the right leg diminished, with complete anaesthesia as far as the ankle-joint. The Achilles jerks present. Knee-jerks present, but weaker on the right side and especially so during the crises. At the height of the crisis it could not be obtained (intermittent loss of knee-jerk). The Argyll Robertson pupil was obtained on both sides with diplopia in certain directions. Romberg's sign absent. Slight lymphocytosis of cerebro-spinal fluid. No history of

syphilis could be obtained from the patient or her husband, but the authors consider the above symptoms sufficient to warrant the diagnosis of tabes dorsalis. The first child died two days after birth from icterus, and the second one six weeks after birth (cause not stated). The disappearance of the knee-jerk at the height of the crisis would be analogous to similar observations as regards the Argyll Robertson pupil phenomenon observed by Erb and Mantoux. Further interrogation elicited the interesting statement that since her first pregnancy the patient had had severe abdominal pains with vomiting and diarrhoea occurring every two months, although she had never so suffered previously. The pregnancies apparently acted as an excitant in a tabetic patient, just as we know that atmospheric changes, fatigue, excess in drink, and coitus may provoke a crisis in a tabetic. Tarnier in his lectures apparently did not recognize tabes as a cause of pernicious vomiting in pregnancy, for he says that one must distinguish between the two conditions, namely, tabetic crises and pernicious vomiting.

GYNAECOLOGY.

107. Treatment of Retroversion of the Uterus.

P. STRASSMANN (*Berl. klin. Woch.*, November 2nd, 1908) states that the estimate that over 50,000 women in Greater Berlin suffer from retroversion of the uterus is not exaggerated. It is, however, questionable whether such a common condition can really be described as pathological. As far as is known, retroversion does not occur in the lower animals. That this is in part due to the upright position of the human being is certain, but it appears also to be due to the fact that women have wider pelvis than other female animals, and the possibility of backward displacements are greater in the former than in the latter. True, such animals as apes have not been subjected to minute examination, which would be necessary to determine whether the uterus is at times tilted backwards. Strassmann points out that all abdominal organs have a dorsal convexity and a ventral concavity. Each organ develops with a flexion forwards. In the upright position the fundus is normally lower than the os. In the cadaver the ligaments are slackened, and the uterus is found to have sunk backwards on opening the abdomen. A sudden misplacement never takes place. Even when the trauma is severe enough to rupture the bladder or to dislocate a kidney, the uterus remains untouched. It may be considered to be the most protected organ in the whole body. Retroversion and retroflexion, which is merely another manifestation of a less pronounced degree of the same condition, either arise as a congenital defect or the false position is gradually acquired. The congenital displacement is present in about one-sixth of all the cases. In the first place, Strassmann mentions a distended bladder as a cause of acquired displacement. The next contributing cause is overloading of the rectum. This levers the cervix forwards, and combined with the backward pressure of a full bladder, which acts on the fundus, the uterus is tilted backwards. These two factors are especially active in lying-in women. The fact that the abdomen has emptied itself of from 5 to 6 kilograms (the weight of the fetus, placenta, and liquor amnii) explains the absence of desire to pass water or to empty the rectum. If no aperient is given, the lying-in woman does not have a motion until the sixth or seventh day *post partum*. The ligaments, and especially the two round ligaments, hold the uterus in its normal anteverted position when other causes tend to disturb this position. A weakening of these ligaments must, therefore, be followed by a failure of natural reposition when the bladder remains full or when constipation continues for some time. The condition of the floor of the pelvis, and the weight of the organ when involution takes place slowly or incompletely also play an important rôle in the genesis of retroflexion and retroversion. Other contributory causes are also mentioned. The author then discusses the results of the displacements. It is a mistake to consider that the uterus alone is turned back. The broad ligaments are thrown out of position with the uterus, and many of the complaints are probably due to this. The first result is that the vessels become twisted, and although the arteries scarcely suffer in their elasticity, the veins become altered and a varicose condition of the ligament results. In response to the venous obstruction, the uterus becomes congested. The posterior lip becomes thickened and bluish, and not infrequently shows an erosion. Menstruation becomes profuse and a catarrhal endometritis develops. Pain arises

from the effort on the part of the uterus to empty its contents against the laws of gravity. The displacement of the ovaries is also important. Follicular haematoma arises, and eventually may lead to adhesions. Small cystic degeneration of the ovaries is not an infrequent find in these cases. The capability of conception and of carrying the fetus is often disturbed. Women with retroverted uteri may conceive, and some of these can pass naturally through the course of pregnancy. Many women under these conditions, however, are sterile, and it is within Strassmann's experience that women have objected to have the retroversion reduced, because they preferred to remain sterile. In Java midwives at times press the uterus into a retroverted position after delivery, in order to produce sterility. This may lead to severe and even fatal inflammations. Next he deals with the retroflexion of the bladder, which follows upon that of the uterus. After dealing with various symptoms which are met with in connexion with displacements he proceeds to discuss the treatment. In cases in which spontaneous correction of the malposition has taken place in pregnancy it is wise to assist matters by giving ergot of rye after delivery or abortion. When the retroversion is due to posterior adhesions following a gonorrhoeal or other inflammatory affection of the tubes, it would be bad gynaecology to attempt a reposition, and, at all events during the early stages, no attempts to deal with the displacement may be made. There is, further, no need to interfere with retroversion in old women. Pessaries may be applied after replacement in suitable cases; and Strassmann believes that, provided no deep tears in the cervix and no unrepai red perineal rupture are present, a case of retroversion taken early may be cured in one year by a ring. He prefers zinc rings to the soft rubber pessaries. Thomas's and S-shaped pessaries are also useful in some cases. When a misplaced uterus has given rise to symptoms which do not yield to conservative dietetic and balneo-therapeutic means, operative treatment should be adopted. Even replaceable misplacements may with justification be fixed in the anteverted position operatively. Ventrifixation yields excellent results. It forms a certain method of curing the condition, and does not disturb a subsequent pregnancy. The operation called "Alexander-Adams's," which consists in shortening and suturing the round ligament in the inguinal canal, can also be utilized for the condition, and leads to good results. It is especially useful when a rupture has to be operated on, as the two conditions can be cured at the same time, and two instruments can be disposed of. When adhesions are present the operation is of no use. With regard to vaginofixation, he points out that disturbances in pregnancy of a serious nature have arisen, and he concludes that the method cannot be recommended. Prophylactically, he advises regulation of the evacuations, especially before and during menstruation. Recent displacements should be detected early, and this implies an examination after every case of lying-in before the patient is discharged as well.

THERAPEUTICS.

108. Antipneumococcic Serum.

G. LANDMANN (*Deut. med. Woch.*, November 26th, 1908) has been experimenting with pneumococci with the object of preparing a powerful antibacterial serum. He found that it was advisable to utilize a very large number of strains, and, adopting a suggestion of Ehrlich's that the bacterial cell possesses variations in the haptophoric groups, he used horses, oxen, and sheep to gain his antibacterial serum, and uses these serums mixed. At first it was assumed that this serum would not be standardizable, but further experiments showed that by using strains which had been increased in virulence and by forcing the immunizing in the horses he was able to produce a serum which lent itself to the usual methods of testing and standardizing. The price of the serum was necessarily much increased by the forced treatment of the horses, as the number of horses which died under the treatment was not inconsiderable. He, however, hopes to be able to reduce this mortality, and consequently the price of the serum, in the future. The value of his serum has been determined as follows: One immune unit is stated to be contained in 1 c.cm., when 0.01 c.cm. of a serum protects a mouse against the effects of an injection of from 10 to 100 times the lethal dose of a living culture applied twenty-four hours later. His serum contains from 10 to 40 immune units per c.cm. He has

further found that his serum acts curatively as well as prophylactically. Animals could be saved if injected with serum from six to eight hours after infection. The usual space of time between infection and death in experiment animals being twenty-four to forty-eight hours, this curative action must be considered satisfactory. He has not come across any strain against which the serum had no influence in animal experiment. So far he has no evidence of its value in human therapy, but he advises its employment in doses of 400 units daily for curative efforts, and one or two doses of 200 units for prophylactic measures. The serum must naturally be employed during the early stages of the various pneumococcal infections, of which he instances ulcer serpens, pneumonia, etc., if success is to be attained.

109. Fibrolysin in Pleural Adhesions.

It is not uncommon that a free deposition of fibrin takes place after the more or less complete absorption of a pleural effusion. This leads to adhesions between the two layers of the pleura, and thus binds down the lung to the chest wall or to the diaphragm. Schnütgen (*Berl. Klin. Woch.*, December 21st, 1908) points out that when the affection is recurrent, as is the case in tuberculosis, an induration of over $\frac{1}{2}$ in. in thickness may be formed. The results of such adhesions and induration on the pulmonary circulation need no special description. The clinical symptoms of such adhesions are diminished breath sounds, loss of vocal fremitus, and dullness on percussion. Pain is complained of. Subjective symptoms may, however, be very slight. The treatment usually adopted in such cases is painting the chest with iodine, applying iod. vasogen, and lung gymnastics, but the results of these forms of treatment are rarely apparent. When gymnastics are combined with fixation of the healthy lung, by means of pneumatic apparatus, better effects are obtained. Since fibrolysin (thiosinamin and sodium salicylate) has within recent times been highly recommended for a large variety of internal and external scar formations, the author determined to try it in pleural adhesions. He used Merck's preparation, which contains 2.3 c.cm. of fibrolysin in each capsule, and injected this dose either locally or into the gluteal muscles. The injections were repeated once or twice every week according to the severity of the case. In the majority of the cases the injections were painless, and the only undesired effects were occasional slight rises in the temperature, slight feelings of tiredness, and headache. The objective and subjective symptoms diminished markedly, and in some cases with extraordinary clearness. In reviewing his cases he states that fibrolysin applied immediately after the effusion is completely absorbed, and signs of beginning pleural adhesions can be made out, is often followed by good results, and should therefore always be tried.

110. Sabromin, a New Bromide Preparation.

V. MERING (*Mediz. Klinik*, September 20th, 1908) has investigated the action of sabromin, the dibromobenzenate of calcium, so called from its analogous composition to that of sajodin, the moniodobenzenate of calcium. The formula of sabromin is $(C_{12}H_4O_2Br)_2Ca$, and it contains 29 to 30 per cent. of bromide. It is a colourless, odourless, and, in contrast to the alkaline bromides, tasteless powder, well borne by the stomach, where it is converted into dibromobenzoic acid, a substance which has no action upon the stomach, and only becomes absorbed when it has passed into the intestine. The author finds the action of sabromin to be less prompt, but more lasting, than that of the alkaline bromides. He considers the drug especially suitable for hysteria, neurasthenia, nervous excitation, palpitation, sense of anxiety, and nervous insomnia. V. Mering usually prescribes 1 gram two or three times daily, but he has given as much as 6 grams daily over a long period. Potassium bromide contains 67 per cent. of bromide, while sabromin only contains 30 per cent., and since the therapeutic effect of the latter equals that of the former, while the dose is about the same, it follows that a smaller quantity of bromide is required when the sabromin is administered. This may partly account for the fact that signs of bromism have never been observed from the use of sabromin, even in animals to whom very large doses have been experimentally administered.

111. Europhen.

IODOPHORM acts by the liberation of iodine in the secretion of wounds, and in consequence is much valued both as a disinfectant and as a stimulant to granulations. The

disadvantages of the preparation include its highly penetrating smell and its toxicity. P. Meissner (*Berl. Klin. Woch.*, August 31st, 1908) points out that even when the odour of iodoform is not objected to, the fact that it is frequently used for soft sores, and that this use is so well known, renders it unsatisfactory to the public. In seeking for a substitute, the chemists have turned their attention to iodized phenols, and in 1901 the employment of isobutyl-ortho-cresol iodide was suggested. This compound is now known as *europhen*. It is gained by allowing a solution of iodine in iodide of potassium to act on an alkaline solution of isobutyl-ortho-cresol. It is a yellow, light powder, possessing a faint odour like saffron. It is insoluble in water, but easily soluble in ether, alcohol, chloroform, and fatty oils. It contains 28 per cent. of iodine. Its physical properties include a capability of adhering well on mucous surfaces and wounds, and in virtue of its lightness small masses are able to cover comparatively large surfaces. Under the influence of moisture, body temperature, and an alkaline medium, iodine is split off, and this, being combined with the secretions, is absorbed and is eventually excreted in the urine. The advantages of europhen as a substitute for iodoform appeared to Meissner to justify a trial, and he therefore applied it in 32 cases of non-infecting chancre. Twelve of these cases were complicated in so far as gonorrhoea was concerned. In all cases it was well tolerated, and the effect was satisfactory. The secretion soon cleared up, the sloughing or dirty surface of the ulcers gave way to healthy granulations, and healing took place steadily. He employed it by powdering a mixture of europhen and boric acid in equal parts every morning and evening by means of a fine paintbrush. The average duration of the healing was between six and ten days. In all cases the powder appeared to diminish the local pain. He has further used it in some cases after the excision of a syphilitic sore. In discussing the action the author states that the splitting off of the iodine is gradual and continuous, and for this reason he is inclined to ascribe special value to the local application. He recommends it strongly.

PATHOLOGY.

112. The Pathogenesis of Tuberculous Neuritis.

G. C. MIRANO (*Riv. Crit. di Clin. Med.*, Florence, 1907, p. 681) discusses the etiology of that somewhat rare complication of pulmonary tuberculosis, the appearance of muscular atrophy and sensory disturbances in the limbs, with loss of the reflexes. These symptoms have been referred by some to peripheral neuritis, by others to changes taking place in the spinal cord (myelitis). Peripheral neuritis has been produced in the lower animals by several experimenters by the injection of tuberculin, and degenerative changes in the anterior cornual cells have been recorded in some of these cases. A few observers have even recorded degenerative changes in the cells of the motor cortex, or in Purkinje's cells in the cerebellum, in cases of pulmonary tuberculosis. Mirano's patient, a man of 19, gave a history of tuberculosis acquired about a year previously in a very dusty flour mill: the symptoms were cough, haemoptysis, night sweats, and wasting. Three months before Mirano saw him he began to complain of pains, formication, weakness, and some rigidity in the legs rendering walking difficult, and he had difficulty in extending his fingers. On examination he showed marked tuberculous lesions at the left apex; a few tubercle bacilli were repeatedly found in his sputa, and he gave a positive tuberculin reaction. He was emaciated, with marked atrophy of the muscles of the thigh, of the tibialis anticus and peronei, of the muscles on the flexor aspect of the forearm, and of the interossei in the hands. Steppage gait was marked, and dorsal flexion of the feet was impossible. Romberg's sign was absent. The plantar, patellar, cremasteric and abdominal reflexes were abolished on both sides, and Babinski's sign was absent. The nerve trunks were not tender, and no trophic changes in the skin were seen: sensation (touch, pain, heat) was not impaired. The reaction of degeneration was well marked in the legs and arms: strong currents were necessary, and ACC was often obtained before KCC. Fever was absent. The patient improved much under treatment by rest, good food, anti-septic inhalations, and galvanism to the extremities. The gait improved much, the knee-jerks and cremasteric reflexes reappeared, the reaction of degeneration was less marked. Mirano argues that this case was undoubtedly one of tuberculous peripheral neuritis. References to the literature are given.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

113. Cheyne-Stokes Respiration.

CHEYNE-STOKES respiration is met with in cerebral, cardiac and renal affections, and in some infections and intoxications. It consists of a series of respiratory movements, at first small and superficial, then more deep and rapid. A progressive diminution in the amplitude and rapidity of these movements then takes place, until complete respiratory cessation accompanied by torpor and somnolence occurs. This respiratory rhythm, due to irritation of the nerve centres, may be observed in organic lesions of the nervous system, such as haemorrhage, softening, degeneration of the vagus nerves, cerebral and cerebellar tumours, acute meningeal affections, and also when there is no organic disease of the nerve centres. In cardiac cases there is no doubt a certain degree of oedema of the nerve centres accompanied by a stimulation of these centres by toxic substances. In chronic renal disease Cheyne-Stokes breathing may appear only in the late stages when the heart becomes dilated, and this fact indicates that by relieving the cardiac dilatation one may cause the Cheyne-Stokes type of respiration to disappear. The most grave form of Cheyne-Stokes respiration, according to Fliessinger (*Journ. des Pratic.*, October 20th, 1908), is that dependent upon chronic renal disease not complicated by cardiac insufficiency. For its treatment one employs the same remedies as for uraemia—blood-lettings, milk and water diet, but these remedies are not often so effective in this condition as in uraemia. Injections of morphine or of heroin, the former in 4 to 5 mg. doses, the latter in 2 to 3 mg. doses, give better results. In acute renal disease the prognosis is less grave. A much less grave form of Cheyne-Stokes respiration is that which occurs in cases of renal insufficiency following on cardiac insufficiency. In such cases of these where the heart is much dilated and there are engorged viscera and oedemas, marked improvement can be obtained. For these cases the proper treatment consists of a reduction in the quantity of liquid taken (Huchard's milk and water diet, 1,500 grams in the twenty-four hours), administration of digitalin in very small doses given for some days, then stopped for a few days and again repeated. Theobromine should only be given when auria is marked, and not before the third or fourth day of treatment. Morphine by subcutaneous injection may be employed, but with the greatest care and caution, but in doses of 2 to 3 mg. is without danger. Morphine calms the dyspnoea and lowers the extreme excitability of the patient. After the fourth or fifth day the milk and water diet may be replaced by broth and cream; then gradually rice may be added to the milk, also cream; potato cooked in water free from salt and boiled eggs may also be given. In Cheyne-Stokes respiration occurring in cerebral diseases the gravity depends much on the extent of the disease. When the disease is limited the altered breathing may disappear, but with extensive disease death is generally quickly brought about. In these cases injections of camphor in oil may be employed. When infections and intoxications are the cause of Cheyne-Stokes breathing it is necessary to direct treatment towards the primary cause. In typhoid fever, diphtheria, small-pox, cholera, and pneumonia Cheyne-Stokes respiration may occur, and in such cases two factors are in action, namely, cardiac weakness and infection with toxic products. In these cases the prognosis is grave; the proper treatment will be to employ cardiac tonics (digitalin, camphor) and diuretics. Certain drugs, such as morphine and the bromides, when used in toxic doses may cause the appearance of Cheyne-Stokes breathing, but with suppression of the drug one may hope for a satisfactory termination.

114. Nutrition and Nervousness in Children.

IN dealing with nervousness in children and the causal part played by malnutrition, F. Siegart states that he only refers to acquired nervousness, and not to inherited cases or to children who have become nervous in response to long-continued illness and consequent nursing and exaggeration of symptoms (*Munch. med. Woch.*, September 22nd, 1908). His cases include children who have been subjected to a special form of strengthening diet. Children who are fed on large quantities of milk to the exclusion of all vegetables,

or on milk and eggs, frequently present a typical picture of anaemia, with loss of appetite, and marked constipation. In analysing his cases he finds that a diet consisting of proportionately too much albumen and fat, and too little carbohydrate, alkali, and cellulose, especially when the total quantity is too small, leads in every case to a marked dystrophy, and in these cases nervousness is one of the most salient symptoms. Diets consisting of an adequate quantity of albumen and fat, with too little carbohydrate and no vegetable or fruit, are not quite so harmful, although these, too, lead to typical dystrophies. He gives a number of examples of these cases, and traces in each case the fault to the improper diet. The author attacks the so-called strengthening diets for children very severely, and attempts to standardize the diets for children between 3 and 10 years of age. With regard to the symptoms of that form of dystrophy in which his nervousness is found, he emphasizes the pale, yellow complexion, the want of appetite, the constipation, the restlessness, and the loss of weight. The treatment of this condition, he says, is very simple. The diet should be one which does not lead to unhealthy fattening, but which can cover the requirements of the children's bodies. Eggs should be excluded, as he finds them unreliable and dear. They may, however, be used in cooking certain dishes, such as puddings, macaroni, etc. Meat should be given once a day after the age of 3 in small quantities, and may be either red or white. Cocoa, chocolate, and husked legumens should be avoided. Milk should be limited in quantity, and may best be given in the form of milk puddings (rice, semolina, barley, and others). When constipation is present the bread should be of coarse-grained flour (Graham, etc.). Fruit, both raw and stewed, with a plentiful supply of vegetables and salads, should form a large part of the diet. He gives further details with regard to the meals which he advises and by means of which he has obtained good results.

115. Alleged Dangers of the Conjunctival Reaction.

TEICHMANN (*Mediz. Klinik*, June 28th, 1908) bases the following conclusions on his observation of 1,500 cases, and on a comparison with the results obtained by others: (1) That the harm alleged to have been caused by the conjunctival reaction depends without exception on the choice of unsuitable tuberculin preparations or on the neglect of important contraindications. (2) That the instillation, in diseased and especially in tuberculous eyes, in the scrofulous, particularly in those of youthful age, and a second time in the same eye, especially with strong solutions, is not permissible. (3) That the conjunctival reaction—undertaken with freshly-prepared solution—is absolutely free from danger, and is at present the simplest means of diagnosing a tuberculous focus, not recognizable by our other clinical methods of examination. The cases observed by Teichmann were all treated with 1 per cent. old tuberculin, and the majority showed only a mild conjunctivitis lasting three or four days. Isolated cases, however, occurred in which chemosis, follicular enlargement, purulent secretion, and subjective sensations of pressure and burning were present. These were limited to the conjunctiva, and disappeared in four to eight days, leaving no trace, and the eyes, after some further months of observation, still gave no sign of conjunctival irritation. Reactions which threaten to be severe are readily checked by the instillation of cocaine 2 per cent. and adrenalin 1 in 1,000. These marked reactions occur almost solely in cases where tuberculosis is clinically manifest, so that the test will not in future be used in such cases, but if it is used, a transient ophthalmia is better than the general disturbances which, in these same cases, would probably occur from the injection of tuberculin. Severe conjunctivitis of long duration, corneal ulcers, iritis, etc., described as having been occasioned by the conjunctival reaction, were in no case observed. Calmette's and Hôchst's tuberculin are inconstant and much too strong. The author advises the use of Koch's old tuberculin in 1 per cent. or at most 2 per cent. solution. Any irritant condition of the urea is an absolute contraindication. Simple chronic conjunctivitis was never made worse, nor did any complication arise, but the test is difficult to determine in such cases. In the literature, harm resulted in no case (with a single unexplained exception) from any other cause than the omission of one or other of the above-mentioned precautions, which we have thus experimentally learnt to be necessary.

SURGERY.

116. Congenital Dislocation of the Hip.

M. FROELICH (*Rev. d'Orthop.*, January 1st, 1909) says that at any age up to about 3 years congenital dislocation of the hip is a malformation which is curable by the manipulative method, and which does not require more than four or five months in the cure. At more advanced ages the treatment becomes proportionately difficult until we are met by cases which have passed the age for which these operations are curative. Here we still continue to fumble. There are three methods open to us for the relief of these cases, namely, the mechanical, the subtrochanteric osteotomy of Kirmisson, and the operative method of forcible abduction of Lorenz and Redard. The mechanical method has given very satisfactory results. It consists of some form of corset with a moulded pelvic piece and thigh piece which retain the leg in a position of abduction, which is the most favourable for fixing the head of the femur. The pelvis-trochanteric muscles shorten and the bone is firmly retained. It is necessary to add to the heel of the boot on the side of the shorter leg. Subtrochanteric osteotomy is indicated when the telescopic movement is large and progressive, when walking with the abducted leg is painful or when lordosis is pronounced. The chief objection to the method of forcible abduction under anaesthetics is the necessity which exists for wearing after operation for months or years a rigid apparatus of moulded leather or celluloid, in order to maintain abduction after rupture of the adductors, which without such apparatus is not maintained. The author gives short notes of 10 cases in which a modified operation had been done after a preliminary extension by weight and pulley. The children were aged 9 to 14; one case was bilateral, the remainder unilateral. There were 2 boys and 8 girls. Extension was used for periods between eight days and two months, with a weight not exceeding 25 kilograms. As a result of his experiences the author is of opinion that the age is not of such great importance as the degree of luxation. When the femoral head is more than 3 cm. displaced from the cotyloid cavity reduction should not be attempted. The state of the muscular system is of enormous importance. When well-developed it is better to abstain from interference, but when weak and small replacement is easy. Again, when the head of the femur is fixed and there is little up and down movement it is not well to interfere. When a weight of from 10 to 12 kilograms is not enough in eight days to bring down the head a distance of at least 1 cm. it is useless to prolong the traction. It will not be tolerated, and there is a danger of bringing about paralysis of the sciatic nerve. He concludes that a few cases which have passed the age limit for the bloodless operation are still benefited by a trial of the method of radical cure.

117. Thyrotomy for Tubercle of Larynx.

SCHMIEGELOW (*Ugeskrift for Læger*, February 4th, 1909) demonstrated before the Danish Oto-Laryngological Society a case of tuberculous disease of the larynx cured by thyrotomy. The patient, a woman aged 49, had been hoarse for about one year, with some cough and expectoration, but no wasting. Six months later a rough infiltration was discovered on the left superior vocal cord, the true vocal cord being fixed. A detached piece appeared, on microscopic examination, to be a typical specimen of flat-celled carcinoma. In the hospital symptoms of phthisis were discovered in both lungs. Thyrotomy was performed after a previous insertion of a Hahn's cannula, and both superior vocal cords were removed by scissors and knife. The inside of the thyroid cartilage was scraped with a sharp spoon, afterwards being sutured with catgut. The microscopic examination now showed typical tuberculous structure. The operation had been performed fourteen months previous to the patient being shown, and she had spent ten months in a sanatorium, where she had gained 17 lb. in weight. The larynx was now found to be scarred and somewhat stenosed circularly; everywhere the mucous membrane was free from tuberculous processes. Had the right diagnosis been made, the exhibitor would not have attempted a thyrotomy, as his previous experiences had shown that any larger operative interference in cases of laryngeal tuberculosis often produced a recrudescence of the lung tuberculosis. He had even lost some cases from acute military tuberculosis. It is possible that in this case the favourable result was obtained first by the energetic, complete removal of the tuberculous tissue and secondly by the primary closure of the larynx without tamponade and the simultaneous removal of the tracheal tube, thereby reducing the post-operative irritation to nil.

118. Post-operative Parotitis.

MARCHETTI (*Rif. Med.*, January 25th, 1909), owing to a recent experience of this condition in two cases (one after an operation for hernia, and the other after an ovariectomy), has given some attention to the subject. The rarity of such cases may be gauged from the fact that only 1 case has occurred out of 10,000 operations in the last ten years. The symptoms are the usual ones described in connexion with mumps, and the cases may be divided generally into three main groups: (1) A mild catarrhal type where the swelling and pain subside in about a week's time without suppuration (about 33 per cent.). (2) A severe and often fatal type where extensive phlegmonous inflammation sets in, with necrosis of tissue, suppuration and probable loss of the gland, and salivary fistula (48 per cent.); this group requires free surgical treatment. (3) A small group (19 per cent.) where some suppuration occurs, but the pus makes its way out through Steno's duct. Adults, especially women (78 per cent.), are more frequently affected than children. Many theories to explain the onset of this particular form of parotitis have been put forward, and the author briefly discusses some of them, laying greater stress on the theory that it is due to exalted virulence in the oral flora, which in its turn is accentuated by the diminished activity of the parotid gland, due to fear, preoperative preparation (purge, altered diet, etc.), diminution in mastication, buccal manipulation by the anaesthetist. But, as the author points out, all these supposed causes are more or less prevalent in every operation, and yet post-operative parotitis is very rare; again, parotitis does not occur as the result of prolonged septic conditions of the mouth. He believes that the parotitis in question is merely post-operative in the chronological sense of the term, and not in any causal sense; that it is not scialogenic in origin, but most likely due to some unrecognized trauma.

OBSTETRICS.

119. Bacteria of Puerperal Uterus.

A. W. W. LEA AND E. J. SIDEBOTHAM (*Journ. of Obstet. and Gynaec. of the Brit. Emp.*, January, 1909) review the present-day knowledge of the organisms found in the vaginal secretions and lochial discharges of pregnant and puerperal women, and give the results of their own investigations as to the bacteria present in the puerperal uterus, and especially as to whether virulent streptococci can in these cases be distinguished from non-virulent ones by the power of haemolysis which they possess. Observers of the organisms found in the vagina during a normal pregnancy have arrived at widely different results. Walthard gives the following list of organisms which have been found: (1) Facultative anaerobic streptococci of the type of *Streptococcus pyogenes puerperalis*; (2) facultative anaerobic diplo-streptococci; (3) anaerobic streptococci; (4) staphylococci of the type of *Staphylococcus albus*; (5) bacteria of the *coli* group; and in rare cases (6) *Bacillus funduliformis*, (7) pseudo-tetanus bacilli, (8) *Bacillus aerogenes capsulatus*. The vaginal portion of the cervix and even the lower part of the cervical canal contain many organisms which do not, however, appear to be able to penetrate the protective zone of the cervical secretion during pregnancy, and all observers are agreed that the cavity of the uterus during a normal pregnancy is free from organisms. During the puerperium a large number of organisms of apparently little virulence are present at the vulval orifice; the vagina is comparatively free during the first twenty-four hours, but later the organisms present during pregnancy multiply rapidly in the alkaline secretion; and, in spite of much difference of opinion, it must be concluded that organisms closely resembling those present in puerperal infection often exist in the upper part of the vagina and in the cervical secretion shortly after delivery, and that spontaneous ascent of the organisms into the uterine cavity is not infrequent. Schottmüller, who has for several years made a large number of observations, chiefly of organisms in the blood in cases of septicæmia, was the first to claim that the virulence of the organism varies with its haemolytic power, and he regards a haemolytic streptococcus as pathogenic. His conclusions have not been altogether confirmed by recent work, since many observers have shown that haemolysis may be produced by organisms of little virulence, although considerable evidence also exists to show that the organisms in severe puerperal infection always show a marked power of haemolysis. Lea and Sidebotham examined the lochial secretions in a series of 58 cases between the second and

ninth day after delivery, and found that organisms were present in the cervical canal cavity of the uterus in 80 per cent. of the cases. It was worthy of note that in 5 out of the 12 sterile cases no vaginal examination had been made during labour. The organisms were mainly those which have been shown to be present in the vaginal secretion during pregnancy; the authors find, however, that there is considerable evidence to show that organisms also ascend from without during the early days of the puerperium. In the great majority of the authors' series of cases the course of the puerperium was entirely uninfluenced by the presence of the organisms. In 20 per cent. of the cases streptococci were cultivated, and in 5 cases these showed marked power of haemolysis. In 4 of the cases in which haemolytic streptococci were demonstrated the puerperium was afebrile throughout; in the fifth case there was a superficial infection of the endometrium with febrile symptoms. The authors, therefore, arrive at the conclusion that the presence of haemolytic streptococci in the vaginal or uterine secretion cannot, in itself, be regarded as an indication of the existence of infection.

120. Grocco's Sign in Pregnancy.

SMITHIES (*Amer. Journ. of Med. Sci.*, October, 1908) records his observations upon 7 cases of pregnancy in which he investigated the value of the paravertebral triangle of dullness (Grocco's sign). The presence of paravertebral dullness in a case of an enormous multilocular cystadenoma suggested the possibility of the occurrence of similar areas of dullness in pregnancy. The patients were all primiparae ranging in age from 16 to 22 years. Five were pregnant between the eighth and tenth month, 1 was fifteen days overdue, and 1 was at the sixth month. A well-marked area of dullness along the spine to the left of the mid-vertebral line was demonstrable in all but 2 of the cases, and these areas were roughly triangular with more or less convex hypotenuses, but the areas were not so distinctly triangular as in cases of simple pleural effusion. The triangles varied in size according to posture, being generally larger with the patient lying on the left side. In 2 of the cases no paravertebral dullness was present, but as one of these was at the sixth month it would be of interest to note whether the sign developed later in the pregnancy. The presence of this paravertebral dullness appears to be due primarily to the abdominal tumour displacing other viscera upwards, and this, in combination with a displacement of the mediastinal tissues by an abnormal arching of the diaphragm whereby the lung may become temporarily moved away from the spine, affords a reasonable explanation of the symptom. In this connexion it is significant that, in the 2 cases referred to in which the sign was absent, in one the uterus had descended just before labour, and in the other the uterus had only reached the size of a six months pregnancy.

GYNAECOLOGY.

121. Retroflexion of the Uterus.

WHILE he realizes that retroflexion of the uterus can cause a number of very definite symptoms and may be the sole cause of a woman's trouble, Max Henkel (*Luench. med. Woch.*, January 26th, 1909) recognizes many cases in which no symptoms or discomfort are produced at all. In forming a diagnosis of retroflexion it is primarily necessary to distinguish the fixed form from the mobile form. The fixed form produces more frequent and severer symptoms than the mobile form, and it is rare for the appendages or pelvic cellular tissue to escape from inflammatory complications in the case of the former. Mobile retroflexion may be practically without symptoms which are noticed by the patient; but Henkel points out that the constitutional or virginal form is a frequent cause of sterility, and that this sterility may be at once removed when the uterus is placed in a proper ante flexion. Some obstetricians believe that the uterus is normally retroflected, but Henkel cannot conceive what reply can be given to the fact that a retroflected pregnant uterus becomes incarcerated unless the misplacement is corrected. He thinks that the gynaecologist should only determine whether sterility is caused by retroflexion by correcting the misplacement and watching whether pregnancy develops. Each case must be dealt with on its own merits. With regard to symptoms, he states that congenital retroflexion only rarely causes any at all, save when marked infantilism or sharp flexion is also present. In these cases the symptoms are those of dysmenorrhoea. The symptoms

are not wholly or even chiefly due to the backward displacement, but can be better explained on the basis of the defective development of vessels, muscles, etc., and for this reason this form is frequently not much relieved by correcting the displacement. In distinguishing between mobile and fixed retroflexion, he advises Schultze's bimanual method and the uterine sound to replace the uterus. The former is only applicable when the abdominal walls are flaccid, so that the hand can be delved well behind the organ. At times it is wise to put the patient to sleep with chloroform for this purpose. This method is not well adapted to primiparae, whose abdominal muscles are rigid and vaginae narrow. The sound should be employed when the bimanual method fails or cannot be easily carried out, but it is necessary to exclude pregnancy and cervical catarrh first. Inflammation of the appendages also contraindicates the use of the sound. No force may be used in attempting to replace the uterus. The whole length of the sound lying within the uterus must touch the anterior wall of the uterus, but the point, which should not be sharp, should not reach quite to the fundus. When the uterus is replaced, provided that no inflammation of any neighbouring tissues is present, a ring pessary may be employed. He prefers Breuss's modification of the Thomas pessary, which has the same curve, but the hind portion is not so thick. Vulcanite, glass, or celluloid all form excellent pessaries. It is important that the pessary fit well—that is, that it is the smallest which keeps in place. In young individuals, however, he finds that pessary treatment should not be employed as a rule. The proper course is to perform the Alexander-Adams operation. He discusses the technique of the operation and some details in the after-treatment. When a mobile retroflexion is complicated with inflammatory conditions or with prolapse of the ovaries, he prefers to perform ventrifixation, and considers that Olshausen's operation is the best. When there is uterine prolapse, the best method is Schauta's vaginoplasty. Details of these various procedures are given, but his accounts do not differ essentially from the accounts published in textbooks and elsewhere.

THERAPEUTICS.

122. Treatment of Syphilis by Atoxyl.

CHARNEILL, BERTIN, AND POITEAU (*L'Echo Méd. du Nord*, October 25th, 1908) have used atoxyl in the treatment of numerous cases of syphilitic disease, and a paper on the above subject gives the results obtained by them. With regard to the physiological properties of atoxyl, the authors point out that the drug is eliminated by the skin and especially by the kidneys, and in some case causes a transitory albuminuria. Elimination, however, is not always rapid, and, like mercury, the drug is liable to accumulate in the system. Koch, Hallopeau, etc., have shown that the drug possesses toxic properties, and its administration may cause headache, vertigo, deafness, fever, vesical tenesmus, retention of urine, and especially blindness. For these reasons it is prudent not to exceed 0.5 gram as a dose, and not to repeat the dose oftener than every other day. Further, it is wise not to continue the drug for more than ten days, then to allow an interval of fourteen days to elapse before entering on another ten days of treatment. When given subcutaneously or injected into the muscles (the two common modes of administration) the drug gives rise to no local disturbance. In many patients whom the authors have treated with atoxyl injections soon after the appearance of the primary chancre they have found that secondary symptoms of syphilis have appeared late, but that the disease has ultimately pursued its usual course. Out of 30 patients presenting various syphilitic manifestations which were treated by atoxyl injections by the authors, in all the general health appeared markedly improved; this, as the authors admit, may possibly have been due to a better condition of life and better hygienic surroundings of the patients whilst in hospital. On the actual syphilitic manifestations atoxyl appeared to have a very slow effect, and primary chancres remained stationary for a long time, in spite of atoxyl treatment. With regard to secondary syphilitic lesions, the authors found that mucous patches rapidly disappeared under atoxyl injections, whilst in other cases of secondary syphilis not very favourable results have been obtained. In tertiary syphilis arrest, and even slight retrogression, of the lesions have been observed; but a complete disappearance of tertiary lesions has never been observed even after long-continued treatment with atoxyl. In all cases in which atoxyl has had very little curative effect treatment by mercury has been

carried out, with the result that all symptoms have rapidly disappeared. As a result of their experiences with the use of atoxyl in the treatment of syphilis the authors conclude that mercury and iodide of potassium cannot be abandoned for atoxyl. They admit, however, that atoxyl has a certain curative effect, and that its employment may be of value in certain cases. However, in the authors' opinions, atoxyl will never become a specific for the treatment of syphilis; its effect in this disease is much inferior to that of mercury, and its toxic effects, especially on the visual apparatus, are greater than those which may result from mercurial treatment.

123.

Treatment of Anthrax.

BARLACH (*Med. Klin.*, November 1st, 1908) has had considerable experience in the treatment of anthrax at Neumünster, a seat of the leather industry. During 1872 to 1900, 10 cases were treated by him, all by the purely expectant method; of these 3 died. During 1900 to 1905, 9 cases were treated surgically. None of these died but recovery was slow. From 1905 to the present time, of 23 cases, treated according to the author's present method, none have died, and the period of treatment required has been short, while there have been no bad after-effects—for example, scars, etc. Barlach's method is as follows:—(1) Rest in bed in every case. This is absolute and rigidly enforced, since it is believed that movement favours the entrance of the bacilli into the blood stream. For the same reason all pressure on the pustule is carefully avoided. (2) In slight cases, fomentations of aluminium acetate or sublimate, the former especially when the pustule is on the face. The author considers cases slight when the disease has remained local, the pustule being situated on an area not markedly hardened, even if there is slight redness and swelling. (3) In severe cases the pustule is slit open, the pointed thermo-cautery is used in a ring of rather deep punctures close together, around the pustule, so that a groove results and this groove hinders the passage of the bacilli from the pustule into the surrounding tissues. The numerous incisions formerly employed were not found to be necessary, and the author now only uses them when there is excessive tension from the oedema. Antiseptic fomentations are also used. In very severe cases, with marked oedema and severe erysipelas, Barlach finds injections of iodine to produce a surprisingly good effect. He injects one or two drops of the tincture at different points on the border of the erysipelas, about 5 to 10 cm. apart, using generally, in all, about 8 minims, or, in very extensive cases, up to 17 minims. This may be repeated, if necessary, in the following days. The author states, in passing, that he has found this iodine injection excellent in cases of ordinary erysipelas, especially of the wandering type. Small abscesses occasionally form at the site of the injection. Camphor injections are also given in severe cases when indicated.

124.

Hypnotic Suggestion in Nervous Pain.

DELIUS (*Med. Klin.*, December 27th, 1908) explains how it is possible to remove so-called nervous pains or psychoses by physical means. The sensation of pain is brought about by a nervous excitation of the neurons in the cerebral cortex (to which the stimuli from the periphery reach) awakening in us the consciousness of pain. Such a neuron-exciting process is called "neurokrym" or nerve waves. Stimuli must be sufficiently intense as well as extensive in order to pass beyond the so-called "stimulus threshold." The height of this varies in different people, in the same people at different times, and at the same time in different groups of cells of the cerebral cortex, which may be in varying conditions of excitability. Modern psychology supposes that it is the ganglion cells of the cortex of the brain—that is, the neurons—which the sensory stimulus reaches, and in which at the same time the remembrance of the stimulus is stored up as a recollected image, a conception. If a neuron receives a similar sensory stimulus often, or if the consciousness of the neuron is frequently awakened through association, then the recollected image will become clearer and sharper with practice, and, in future, an ever-decreasing stimulus will be sufficient to awaken the recollected image—that is, the stimulus threshold becomes ever lower. Since the conception is only the impression of the sensation, and differs only quantitatively, not qualitatively, from the sensation, it is clear that a conception may exist through associative stimulation, if the nerve waves are only strong enough to lead to sensation. This is called hallucination. Hysteria may be the result of the persistence of hyper-excitability of certain neurons after the disappearance of

an organic cause. It is often a case more of primary over-stimulation of the neurons combined with a prohibition of restraint, the state of mind playing an important part. The emotional idea of a diseased condition is by itself sufficient to produce the latter. Nervous pains are due to illusions and true hallucinations rather than true sensation, and therefore can be removed by psychical measures. It is a case of illusion when peripheral sensory stimuli, which ordinarily cause no painful or no sensation at all, are interpreted by over-excitable centres as pain. Delius has successfully treated facial and brachial neuralgias, sciatica, cardiac pain, and migraine by psycho-therapeutic measures. In a case of trigeminal neuralgia, first right, then left, or always symmetrical, one should first think of a psychalgia. Signs of neurasthenia or hysteria will also be present. Delius dealt successfully with 60 cases of disturbed menstruation by hypnotic suggestion; the pain during a period ceased or became much less, in cases where the flow previously lasted too long the duration was shortened, excessive loss was reduced, and the onset of menstruation brought about earlier or later as required. Suggestion may prevent the consciousness of pain even of organic nature, and Delius twice brought about a practically painless confinement, but pain of organic origin cannot be removed for long. Delius concludes that anomalies of menstruation are largely due to the co-operation of cerebral causes. Perfectly healthy women have practically no pain during the period. Local inflammation causes pain, and, owing to the monthly recurrence of the period, such a condition of over-excitability of the neurons may be gradually brought about, fear playing an important part; finally, even after healing of the local affection, the normal flow may overstep the stimulus threshold, and call forth consciousness in the form of pain; and, on the other hand, it may produce further nervous paths which lead to an abnormally severe flow. In hypnotic treatment by suggestion, the over-excitability of the affected system of neurons is lowered, and thus their stimulus threshold raised, so that in future neither stimuli reaching them from the periphery nor the association of sensations connected with the idea of the disease will be in a position to produce painful signs of consciousness. One will then try by direct suggestion to bring about a momentary prohibition of perception, success varying with the suggestibility of the patient and depth of the hypnosis. Through the removal of pain by suggestion, the distrust of the patient disappears, and more powerful association channels in a better direction are produced. The more powerfully these innervation waves incite in the direction of healing the sooner are they in a position to prohibit the over-excitability of the diseased neurons maintained by fright. If one explains to the patient that precisely the anxious consideration of his condition is harmful, his conception and the impulse of his will in the right direction will help to strengthen the recovery. Delius maintains that one should desist from the use of hypnotism in all such suitable cases only when it cannot be attained, instead of reserving it for cases which defy every other therapeutic measure.

PATHOLOGY.

125.

The Blood in Gonorrhoea.

SARRA (*Gazz. degli Osped.*, No. 104, 1908), in view of the well-known clinical aspect (fever, pallor, general malaise, etc.) often associated with acute gonorrhoea, has carried out certain researches on the state of the blood in this condition. His conclusions are as follows: (1) In the early days of acute anterior urethritis the red corpuscles and the haemoglobin vary within limits that may be considered normal, but when the whole urethra is affected there arise signs of slight anaemia (diminution in the haemoglobin and number of red corpuscles). (2) More marked changes are seen in the white corpuscles, which tend to reach figures above the normal, and if the urethritis is total, and especially if there are complications, a definite hyperleucocytosis is present. (3) This hyperleucocytosis is almost entirely made up of polynucleated neutrophilic cells. If these descend to the normal or below, then there is a larger number of eosinophiles. (4) The eosinophiles in anterior urethritis vary within normal limits: in total urethritis they are increased in number, and that may occur either at the acme of the disease or during defervescence. (5) In chronic urethritis the blood formula varies within the normal limits. These facts confirm the clinical view that during the acute stage of gonorrhoea there is a certain amount of general infection.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

126. Haemorrhagic Purpura.

LENOBLE reports the following case (*Arch. des Mal. du Cœur, des Vaisseaux et du Sang*, August, 1903): A painter, aged 16, was admitted to hospital on May 4th, 1903. About one month previously he had fallen on to his back, and a few days later complained of pain over the region of the kidneys. Ten days after the fall he suffered from violent pains in the abdomen and legs, and the following day vomiting and severe diarrhoea set in, the stools containing blood. Repeated attacks of epistaxis occurred, together with bleeding from the gums. The patient was feverish and delirious. Red spots then appeared on the arms and legs, and the abdomen became distended and painful to palpation. On the fifteenth day following the accident the patient passed bloody urine. When admitted to hospital he was found to be a well-developed man: the mucous membranes were of a good colour and the skin slightly icteric; the abdomen was distended and painful; there was no oedema of the limbs. On percussion, there was slight dullness found in the flanks, the rest of the abdomen being tympanitic. The tongue was pale, the appetite very bad; vomiting had stopped, but diarrhoea still persisted, although no blood was seen in the stools. Heart and lungs were healthy. The urine was of a deep red colour. On rectal examination there was to be felt behind the bladder a hard mass. Slight attacks of epistaxis occurred from time to time. On May 20th a confluent purpuric eruption appeared on both forearms and both legs. From this time the abdomen ceased to be painful, but signs of ascites appeared. Diarrhoea ceased and the stools became of a putty colour. Signs of fluid in each pleural cavity at this time occurred. By June 1st the purpuric eruption was clearing up, but the ascites was increasing and oedema of the legs and scrotum appeared. On June 5th a fresh attack of purpura occurred; this, however, had completely disappeared by the 11th; the urine contained a large quantity of albumen and, on centrifugalization, red cells. The examination of the blood on May 23th showed well-coloured red cells and numerous haematoblasts; the white cells were abundant. The coagulation time of the serum was ten minutes. The serum was alkaline in reaction and did not give a positive Gmelin reaction. A differential count of white cells showed the following: Polynuclears, 71.2 per cent.; lymphocytes, 25.5 per cent.; mononuclears, 3.3 per cent.; eosinophiles, 0.4 per cent.; mast cells, 0.1 per cent.; transitional forms, 1.7 per cent.; no myelocytes. The red cells exhibited neither poikilocytosis nor polychromatophilia, and no nucleated red cells were seen. On June 5th the red cells numbered 3,162,000, the white 10,330, and large numbers of haematoblasts were present. There were no nucleated reds. The differential count of white cells gave much the same result as on the first occasion.

127. Muscular Rheumatism.

EMIL SCHWAB (*Zentralbl. f. die gesamte Therap.*, October, 1908) deals with the subject of muscular pains under three headings: (1) Muscular pain due to affections of the muscles which are preceded by some pathological process in the nervous system, as, for example, the pain of the cramps which are an expression of the alcoholic diathesis; (2) muscle pain accompanied by anatomical changes in the muscles, as in purulent or haemorrhagic acute polymyositis, or in the acute simple or rheumatic polymyositis, the symptoms of which are high fever and severe muscular pain; (3) pain not accompanied by any obvious pathological anatomical change in the muscles. Cases belonging to the third group are those frequently met with, and, since within the group are included many different conditions whose common characteristic is the muscular pain, the author would prefer to give to them the name "myalgia" rather than the more pretentious ordinary name of "muscular rheumatism." The diagnosis of myalgia needs considerable care: it is not enough that spots painful on pressure should be found on the muscle, but the body of the muscle must be painful in its whole extent. Where the muscles of the trunk are in question it is not always easy to differentiate hyperaesthesia of the skin from myalgia. In connexion with rheumatic torticollis and lumbago, Schwarz puts forward the views of Erben. Erben finds that in

rheumatic torticollis the pain is on the convex, not on the concave, side of the neck, and he considers it to be caused by the distortion of the cervical spine, and thus to be a joint affection rather than true myalgia; similarly lumbago, according to Erben, is either a neuralgia or caused by an acute distortion of the joints; the author is unable to agree with this explanation of lumbago in all cases, because of the permanent benefit which he has often seen result in lumbago from the application of strong faradic currents. Abdominal myalgia is often the cause of a mistake in diagnosis: in one case which came under the author's notice myalgia was diagnosed as cholelithiasis, while in another the patient was treated for myalgia, but died of perforation of an ulcer ventriculi. In testing for abdominal myalgia the author's practice is to put his hand upon the rectus muscle while the patient is lying down; the patient then sits up, the muscle contracts almost against the investigating hand, and in cases of myalgia there is acute pain. Errors may still arise, either because the muscular contraction has an irritating action upon the deeper lying muscles, as is perhaps the case in abdominal colic, or because hyperaesthesia of the skin may occur, as in appendicitis or cholelithiasis. The diagnosis of other forms of muscular rheumatism is also considered. Finally, Schwarz points out that the pain of myalgia is not always most severe after movement, but is very often worse at night in bed. Women at the time of the climacteric are very subject to nightly exacerbations of myalgia, often accompanied by acroparaesthesias of the fingers and legs; the association of symptoms suggests the possibility that the seat of the disease is not in the muscles, but that the muscular pain depends upon an abnormal nervous and vasomotor condition.

128. The Ophthalmic-reaction to Tuberculin.

A COMMUNICATION on the ophthalmic-reaction, which was intended for the meeting of the German scientists and physicians at Cologne, but which the author, A. Wolff-Eisner, was prevented from delivering there, was read at the Tuberculosis Congress at Washington, and is published in the *Muench. med. Woch.*, November 10th, 1908. With regard to the subcutaneous application of Koch's tuberculin, Wolff-Eisner states that while a positive reaction obtained by its means indicates the presence of tuberculosis, it by no means indicates that the disease is active. Positive reactions have been obtained in from 50 to 80 per cent. of persons who were apparently healthy. The cutaneous reaction seems to correspond fairly exactly. It is a handy and safe method of applying tuberculin for diagnostic purposes, but it discovers inactive and latent tuberculosis as well as clinically manifest tuberculosis. The conjunctival reaction, on the other hand, is capable of determining an active form of disease. It is positive in active tuberculosis, save in advanced stages. Healthy persons are said not to react to it, some apparently healthy persons react, and have been shown later to have been tuberculous; and, further, that some 5 to 8 per cent. have shown a positive reaction, but the future may show that they, too, were tuberculous. From this he concludes that apparently healthy persons who show a positive ophthalmic-reaction to tuberculin should be suspected of tuberculosis. The value of the reaction lies in the positive responses; negative results do not exclude active tuberculosis. It is, in his opinion, not a focal reaction, and in this fact its safety lies. The danger of a general reaction does not lie in the rise of temperature which manifests it, but in the fact that tuberculous foci respond to the introduction of the tuberculin. If the contraindications of the ophthalmic-reaction are strictly adhered to, there is no risk attaching to its employment. These include the avoidance of applying the tuberculin to an eye affected with tuberculosis, and of repeating the test in the same eye. Concentrated preparations should not be used. The author uses a special tuberculin, called "Ruefe-Enoch" in from 1 to 2 per cent. solution. He complains that ophthalmologists, who are in a specially good position to determine the value of the test, habitually neglected these contraindications. It has been stated that the reaction is unreliable. Wolff-Eisner states that those who say this are not good clinicians. Negative reactions in obvious cases of tuberculosis are indications of a bad prognosis, but the reverse does not hold good. Further, he considers that progress can be materially

assisted by a comparison of the ophthalmic and cutaneous reactions. In comparing the reaction with opsonin as a diagnostic and prognostic means, he has come to the conclusion that in spite of the very laborious technique involved in determining the opsonic index, this does not yield more information than does the ophthalmic-reaction. He states that his opsonin experiments, and also his experiments with complement deflection, have proved that tubercle toxin, corresponding in every way with tuberculin, is absorbed by every tuberculous patient. This means that an injection or other application of tuberculin cannot do more than the progress of the disease can do, and that when a patient has reacted to an application of tuberculin, it is open to the observer to ascribe the changes in the tuberculous foci either to the artificially-introduced tuberculin or to the tuberculin produced in the disease focus itself. He believes that various tissues are capable of producing receptors which combine the tuberculin, and thus localize the toxic action. This idea has a practical importance, inasmuch as it is possible to produce the receptors in connective tissue or in the skin by means of tuberculin injections or inunctions, which may attract the tuberculin produced in the pulmonary foci to itself.

SURGERY.

129. Intestinal Surgery.

The fifth *Bulletin of Research Work* in the Division of Surgery of the Medical School of Harvard University, published in December, 1908, contains four reports of experimental work on novel questions in intestinal surgery. Cannon and Murphy, in a paper on *The Movements of the Stomach and Intestines in some Surgical Conditions*, give the results of fluoroscopic observations made after operations on these viscera by means of the Roentgen rays. It is stated that after high intestinal section and suture gastric peristalsis is not interfered with. For about six hours after the operation the pylorus remains tightly closed against the peristaltic pressure of the stomach, and does not permit food to pass into wounded gut. There is a striking coincidence, the authors believe, between the duration of the delay of the discharge from the stomach and the period of the primary cementing of the intestinal wounds. After end-to-end suture of severed intestine no inefficiency of the gut at the seat of suture was observed, but after lateral anastomosis, on the other hand, there was always an accumulation of food in the chamber formed by the apposed loops. From this latter result, which is attributed to prolonged failure of co-ordination of the divided circular muscles, it is concluded that lateral anastomosis is not so ideal an operation as end-to-end union. In cases of intestinal obstruction the food, it was found, leaves the stomach without delay, and, after accumulation and subjection to turbulent movements of peristalsis at the seat of the obstruction, is swiftly returned to the stomach. After thrombosis and embolism there is usually no movement of either stomach or intestine, the food lying quiet in the former viscus until discharged by vomiting. Post-operative paralysis of the alimentary canal is due, it is held, but in a slight degree to prolonged etherization, and to exposure and chilling of the gut. The delay in the passage of food was found most marked after handling of the digestive organs, which, even when gentle, was followed by a temporary arrest of the movements of the stomach. In his conclusions from a *Clinical and Experimental Study of the Use of Sterile Oil for the Prevention of Intra-peritoneal Adhesions*, Blake holds that it is fair to assume that olive oil, absolutely sterile, may be used in the peritoneal cavity of patients in moderate quantities (1 to 4 drachms) without danger, general or local; that it remains in the cavity for periods varying from five to fifteen days and possibly even longer; that its presence tends to prevent early and direct adhesion of denuded or inflamed peritoneal surfaces, and, therefore, that its use under certain precautions is indicated as being moderately effective in sometimes preventing and usually diminishing the formation of post-operative peritoneal adhesions. The author states that special care must be taken in sterilizing the oil, which is not done by some methods in common use, and mentions that in two of his clinical observations very unpleasant symptoms occurred. It seems probable, moreover, that this method would not be free from the danger of fatty embolism. In a paper by Monks on *Flushing the Intestinal Canal with Salt Solution through Multiple Enterotomy Openings*, the author concludes, from experiments on animals and the human cadaver, and also from the favourable results obtained in one case of grave streptococcal peritonitis, that this pro-

cedure is likely to have in certain cases a distinct sphere of usefulness. It is argued that when a patient's life is in danger from acute intestinal poisoning associated with much distension of the bowels, and the time has passed when ordinary methods are likely to be of any use, there is a fair possibility that the immediate removal through enterotomy openings of a part of the intestinal contents, and flushing the intestinal canal with a quantity of warm saline solution from one opening to another, may turn the scale in favour of the patient and save life. The following suggestions are made on the technique of this procedure: A loop of bowel is picked up high in a median laparotomy wound made from the pubes up to or above the umbilicus. The upper and lower ends of the loop having been determined by reference to the root of the mesentery, a small opening is made in the loop. After a free escape of gas and faeces a small glass tube is inserted through the enterotomy opening and directed downwards towards the ileo-caecal valve. Some of the intestinal loops below the opening are now gently distended by warm saline solution. If nothing more than this can be done, the substitution in the bowel of the warm salt solution in place of the gas and faeces that have escaped will, the author thinks, presumably help the patient. If the patient's condition will allow it, a second opening should now be made in the loop which is apparently the lowest of those distended. A glass tube is passed through this and the portion of intestine between the two thoroughly washed out, until the solution running away through the tubes is quite clear. The first enterotomy wound is next cleansed and sutured, and the portion of intestine that has been washed out returned into the abdominal cavity. This procedure is repeated on the lower bowel, unless further action is prevented by the patient's condition. Finally, if the condition permits, the colon is filled with the saline solution from the lowest opening in the small intestine, and a tube is introduced into the rectum to remove any of the solution or of intestinal contents that may reach the lower bowel. In the final paper on intestinal surgery, Scudder states that he has undertaken laboratory experiments in order to determine the behaviour of the bowel after it has been deprived of its mesentery and the omentum has been used to take the place of the mesenteric blood supply. The results of his own, together with those of other investigators, have led him to regard this procedure of omentopexy to a portion of bowel detached from its mesentery as of very limited usefulness in human intestinal surgery. Resection and anastomosis of the bowel remain the procedures to be adopted to the conditions following a removal, accidental or intentional, of the mesentery from the bowel. It is conceivable, however, that an omentopexy, especially if made to either side of the denuded area, might prevent necrosis if a limited portion of intestine (2 or 3 cm.) were deprived of its mesentery.

130. Laryngeal Cyst.

KLEIN (*Ugeskrift for Læger*, February 4th, 1909) reports an unusual case of laryngeal cyst. The patient was 74 years old, and had suffered from increasing hoarseness for about nine months, and during the last month from nocturnal suffocation symptoms. The voice was alternately toneless and rough and vibrating. The laryngeal mucous membrane was diffusely red and so much swollen anteriorly as to hide the vocal cords, which posteriorly were greyish-white and fully movable on inspiration. During phonation they were separated for a considerable distance, as a smooth tumour, seemingly of the size of a bean, was pressing upwards, filling the anterior two-thirds of the laryngeal aperture. Its exact position could not be determined on account of the swollen condition of the mucous membrane. It was easily removed by the endolaryngeal method under cocaine-adrenalin anaesthesia after Parker's method, by means of the cold snare, some force being necessary. The tumour was smooth, sausage-shaped, 2½ cm. long and 1 cm. in section. Its stalk was found to have been attached to the anterior third of the right superior vocal cord. It had thus been hanging down into the rima glottidis, so that only its tip was visible on strong expiration. The microscopic examination showed that its distal rounded part contained a cyst filled with serous fluid, its wall consisting of connective tissue sparsely infiltrated with cells, this tissue being directly continuous with that of the mucous membrane, and its free surface was continuously covered with similar surface epithelium. The cyst appears to have arisen by retention in one of the glands of the mucous membrane affected with chronic catarrh. Laryngeal cysts are most common round the lig. glosso-epiglottica, and are as a rule broad-based. The author has not found any similar case of stalked laryngeal cyst reported.

OBSTETRICS.

131. Dystocia from Circular Vaginal Septum.

LÉPAGE (*Comptes Rendus de la Soc. d'Obstét. de Gynéc. et de Pédiatr. de Paris*, November, 1908) attended a labour where the first stage was obstructed by a diaphragm placed transversely in the vagina. The patient was a primipara, aged 18, the last period occurred in the middle of September, 1907. In the middle of the eighth month Lépage was consulted by her doctor. The vagina was tender and an anaesthetic had to be given before the parts could be examined properly. The hymen, lacerated, was partly persistent. Above, half-way up the vagina, some white cystic bodies, each of the size of a haricot bean, were discovered and laid open; they were thin-walled and contained sebaceous matter. Immediately superior to these cysts was a well-developed transverse diaphragm, thickest posteriorly. There was a small central orifice into which some cystic bodies, like those below the septum, projected. The cervix with the fetal head presenting, could be plainly defused. Thirteen days later, on June 24th, 1908, labour pains began at 8 a.m. By 11.40 p.m. dilatation of the cervix and of the vaginal diaphragm was complete, and one hour later a live female fetus over 6½ lb. in weight was delivered spontaneously. By July 23rd the diaphragm was represented by a cicatricial ring hardly constituting a stricture; it lay 1½ in. above the vulva. The cervix was free from any bands running across its fornices. The transverse vaginal septum is a condition normal in some of the lower mammals. When it complicates labour the fetal head generally dilates and tears the septum without the aid of obstetric art. Pinard, in discussing Lépage's case, observed that he had seen a great number of instances of circular transverse vaginal diaphragms obstructing labour, but in no instance did he find it necessary to intervene. When there was a longitudinal vaginal septum, the presenting head usually pushed it aside; but in a breech presentation the legs of the fetus tended to get astride the upper border of the septum. On that account Pinard always applied two forceps to the septum and divided it between them.

132. Aisol in Gynaecology and Obstetrics.

PINNER and SIEGERT (*Med. Klin.*, December 27th, 1908) recommend aluminium-aceto-tartrate (which the firm Attenstedt and Redeker have called aisol) as an antiseptic which (1) is non-poisonous, (2) does not corrode, (3) does not stain linen, (4) is transparent, (5) does not smell disagreeably, (6) has no action on indiarubber tubes. It is prepared by dissolving 2½ parts of basic aluminium acetate with 1 part of tartaric acid in water, filtering and evaporating to dryness. Colourless, shiny, gummy lumps are obtained, which smell faintly of acetic acid, and, when diluted with water, give a colourless mass of the consistence of syrup. The statement that aisol is non-corrosive refers only to the diluted solution in which it is commonly given to patients. When concentrated it is highly astringent and corrosive, and may be used instead of Paquelin's cautery. It is excellent in the treatment of erosion of any kind and ectropion, and is useful for douching the vagina during treatment by pessaries and as an after-cure in acute gonorrhoea. As an intrauterine douche after curetting following abortion, it causes immediate contraction of the uterine muscle, and is very useful in chronic parametritis and specially painful chronic forms of pelvic peritonitis. It may be heated to at least 60° C. without decomposing, and will disinfect instruments and apparatus. Aisol dusting powder is excellent for powdering the hands before a gynaecological examination; thus a discharge may be diagnosed by digital examination alone, which is not possible when a fatty or oily material has been used. By experiments with anthrax and Neisser's gonococcus, etc., Aufrecht showed that the disinfecting power of aisol is more than twice as great as that of liquor aluminium acetatis and very slightly greater than that of carboic acid.

GYNAECOLOGY.

133. Congenital Diaphragmatic Hernia.

SCHREIDER (*L'Obstét.*, August, 1908) attended a woman who was delivered of a female child spontaneously. The infant cried once and then turned blue; the pulsations of the heart were perceptible on the right side of the thorax. The child died, and radiography was undertaken at once. A left diaphragmatic hernia was discovered. Schreider

inquired about the family history. The mother's first pregnancy was gemellar. A boy and girl were born, the former had a right inguinal hernia. Two years later a daughter was born, who also had a right inguinal hernia. At the end of four years a boy was born with umbilical hernia and ectopia of the abdominal viscera. Lastly came the girl with diaphragmatic hernia. The mother's father was subject to double inguinal hernia, and had a twin sister. The mother had six brothers and four sisters all in good health, but two of the sisters had undergone operation, the one for single, the other for double, hernia, the variety not being specified. The mother's father, mother, sisters, and three out of her six brothers were all subject to varicose veins, an interesting fact, Schreider remarks, in association with the tendency to weakness of the abdominal walls so marked in her relations.

THERAPEUTICS.

134. Treatment of Bronchial Asthma.

SUCCESS in the treatment of bronchial asthma depends on a proper estimation of the condition. The treatment necessarily falls under two heads: That of the acute attack and that of the "disposition." G. Treupel (*Deut. med. Woch.*, December 31st, 1908) first discusses those processes which lead up to an acute attack. The chief symptoms are air hunger, spasmodically prolonged expiration, and frequently a feeling of pressure on the chest, which may amount to actual pain. There may be some pressure symptoms heralding the attack. Fear is associated with the attack. Physical examination reveals loud sibilant rales; the auxiliary muscles are used for respiration, and the expiration is laboured and slow. The heart and pulse are remarkably little affected. The lungs are found to be in a condition of over-distension. Towards the end of the attack there is usually some thick, mucous sputum. When this is got rid of, a freer type of breathing takes place. The patient usually feels well between the attacks, and capable of undertaking exerting work. The causes of the attack are: First, a narrowing of the finer bronchial tubes, and secondly, a secretion of mucus in response to dilatation of blood vessels in the bronchi. The former is a muscular spasm, which depends on some irritation of the vagus, and the second is due to vasomotor changes. It thus appears that both determining causes act through the nervous system. Pressure on the vagus is capable of calling forth an attack of asthma (for example, by a tumour). It has been found experimentally that an asthmatic attack produced by irritation of the vagus can be stopped by paralysing the nerve endings with atropine; ½ to 1 mg. of atropine injected subcutaneously stops the stormiest symptoms of an attack in from ten to twelve minutes. The old burning powders contained atropine. The action of Tucker's secret remedy depends largely on this drug. Treupel calls attention to the analyses of this preparation, and medical practitioners will do well to write their own prescriptions according to the one or other formula. Einhorn's analysis was:

Cocaine nitrite	1.0 per cent.
Atropine nitrite	0.6 "
Glycerine	32.2 "
Water	66.2 "

The percentages are approximate.

Bertram's analysis was:

Atropine sulphate...	...	0.15 gram
Sodi nitrosi	0.60 gram
Glycerine...	...	2.00 grams
Aque	15.00 grams

If the solution prepared according to the analysis of Bertram is sprayed for three minutes, from ½ to 1 mg. of atropine will be absorbed from the tracheal mucosa. Ritsert's inhalation fluid contains anaesthesin, atropine, belladonna, saltpetre, and stramonium. This is known as *eupneuma*. Trousseau introduced a preventive method of treatment by giving a pill containing ½ mg. of atropine daily, and increasing the dose by ½ mg. every second or third day until 4 mg. were reached. The treatment was continued for four weeks. Morphine also does good in the acute attack. The dose must not be less than 1 cg. This can with advantage be associated with ½ mg. of atropine; 2 grams of chloral hydrate also works well. Next the author turns his attention to the reflex neuroses, and especially those originating in the digestive organs, sexual organs, and nose. It is naturally necessary to remove the cause of irritation, whenever this is possible. When the attack is due to the reflex action of certain

forms of dust or volatile substances acting through the nasal mucous membrane the latter should be cocaineized. The asthmatic is usually very dependent on psychic influences. The remembrance of circumstances accompanying a previous attack may give rise to a renewal of the malady, when these circumstances are repeated. Fear and other forms of nervous disturbances, especially at night time, predispose to an attack. The fear of choking often leads to a wrong irregular form of breathing, and it is quite possible to produce an attack willingly by imitating this form of respiration. Treatment which influences the fear of choking and which regulates the respiration is of importance. The author goes into some detail with regard to the psychical treatment of asthmatics. Lung gymnastics, either by means of the Swedish system or by special apparatus, require to be employed in certain cases. The effect of climate is also important. In some cases sea or mountain air permanently cures. The catarrh connected with asthma is best dealt with by means of sweating, either with iodides or without. Electric-light baths form the best method of applying the sweat-producing agent. A handy form has recently been introduced which permits of the bath being given in bed under a cradle. In conclusion, Trempel states that the treatment of asthma is a grateful field for the practitioner, but is by no means an easy one. It depends largely on the knowledge and capabilities of the practitioner and on his will and perseverance.

135. Cutaneous Tuberculin Reaction in Infants.

ELLENBECK (*Mediz. Klin.*, October 18th, 1908) had 232 infants in the Dresden Home for Infants vaccinated cutaneously with tuberculin in the way Pirquet recommended, regardless of the disease present, to show whether the cutaneous test proved always negative in non-tuberculous children, and positive in the tuberculous. The practical results show that: (1) The cutaneous reaction is a valuable aid in the diagnosis of tuberculosis in infants, since it is harmless, simple, and trustworthy. (2) A positive reaction is often the first sign of incipient tuberculosis, and can therefore increase our knowledge of the course of tuberculosis in infants. (3) A reaction is only to be counted as positive when a distinct red papule forms; doubtful reactions are to be included as negative. (4) The negative reaction is often of great significance: a negative result of the cutaneous test is only to be held of value after several repetitions at suitable intervals (fourteen days). (5) A positive reaction occurred 5 times amongst the 232 unselected infants vaccinated, and showed that tuberculosis of infants, even in previously thriving children, offers a bad prognosis. The author gives notes of the tuberculous 6 cases in which the Pirquet treatment was tried, 5 proving positive and 1 negative. In 1 case the patient was $\frac{3}{4}$ months old, mother tuberculous, infant artificially fed since fourteenth day. January 19th: Condition—weakly, badly nourished child; skin, greyish-white; anxious expression, restless; respirations accelerated and deepened left lung, posteriorly and below; prolonged and heightened respirations; no fever. January 20th: Result of yesterday's cutaneous reaction strongly positive; around the vaccinated spot near the elbow an area has formed, larger than a 3-mark piece, of papules, the size of a pin's head, thickly set on a red ground. January 21st: Death following convulsions. Section: Caseous bronchial glands; fresh crop of fairly numerous tubercles in lungs, liver, and spleen; mesenteric glands not noticeably swollen.

136. Endovenous Injections of Corrosive Sublimate in Acute Rheumatism.

OSTALI (*Gazz. degli Osped.*, August 16th, 1908) records three cases of acute polyarticular rheumatism which, after proving rebellious to salicylate treatment, improved quickly under endovenous injections of corrosive sublimate. The first case was that of a man aged 22, admitted on February 21st with acute rheumatism (feet, knees, and ankles). Sod. salicyl. and caffeine were given, salicylic packs applied to the joints: after about a week of this treatment, no benefit being observed, on March 2nd an endovenous injection of 5 mg. of sublimate was given; the next two days the patient was much better, pains relieved, and temperature lower. On March 4th a slight relapse occurred, and another injection of 5 mg. was given. March 9th, 10 mg. were given. After this no further treatment was required, and the patient was discharged cured. The other two cases (aged 29 and 52) derived similar benefit. In the second case the patient became apyretic the day after the first injection, and remained so. No ill effects were observed.

PATHOLOGY.

137. Experimental Reduction of Kidney Substance.

PEARCE (*Journ. of Exper. Med.*, September, 1908) finds that removal of one-half, two-thirds, and sometimes three-quarters of the kidney substance in the dog causes no change in the general nitrogenous metabolism as determined by estimations of the total nitrogen, urea, and ammonia eliminated by the urine. The removal of larger amounts, and sometimes of three-quarters of the substance, leads to the condition of metabolism associated with starvation. This, however, is apparently the result of the gastro-intestinal disturbance constantly associated with extensive kidney reduction, and not of a disturbance of general nitrogenous metabolism. The determination of the amount of faecal nitrogen indicates that the gastro-intestinal disturbance is not due to diminished absorption; and only in one experiment was there evidence of its being due to an increased elimination of nitrogenous substance into the intestine. Pearce argues that the results of his experiments are against the theory that the kidney furnishes an internal secretion which has an important influence on general nitrogenous metabolism. At least, if such a function exists, it is not disturbed by the removal of three-fourths of the kidney substance.—Sampson and Pearce (*Journ. of Exper. Med.*, November, 1908), in a further research on experimental reduction of the kidney substance, find that the immediate effect of the operation on the portion of the kidney remaining is an infarction of the tissue compressed by the sutures. The area of necrosis extends only a short distance into the adjacent kidney tissue. The infarction gradually becomes replaced by fibrous tissue, and in three to four weeks' time the necrotic tissue entirely disappears. The amount of fibrous tissue in time becomes so slight and the healing so perfect, that it is difficult to detect the site of the operation. The renal elements sometimes persist in the infarcted area, and the glomeruli apparently are more resistant than the tubules. The tubules in this area sometimes become calcified, and bone formation beneath the epithelium of the pelvis is also of frequent occurrence. The pelvic epithelium usually shows marked proliferation, and may invade the field of operation in alveolar masses. In two experiments removal of approximately half of one kidney did not alter either the remaining portion of that kidney or the size of the opposite kidney: these experiments were terminated on the thirty-fourth and forty-seventh days. In another experiment, terminated in twenty-one days, there was a slight but definite atrophy of the remaining tissue of the kidney operated upon. In six experiments in which one kidney was removed and approximately half of the other, three of the animals died as a result of the operation on the sixth, seventh, and tenth days. The probable cause of death was renal insufficiency. The animals refused food, vomited persistently, and lost strength and weight. The other three animals recovered, and were killed at periods varying from five to eight weeks.

138. Complement Fixation in Mothers of Syphilitic Infants.

KNOEPFELMACHER and LEHNDORFF (*Mediz. Klinik*, August 2nd, 1908) think it highly probable that the mothers of syphilitic infants have, as a rule, had syphilis themselves. This belief is based on their observations of 45 women, the mothers of children admitted into hospital for hereditary syphilis. Of those mothers who showed no signs and gave no history of syphilis (32) reaction was positive in 18 (56.2 per cent.). Of those who had had syphilis (13) 8 gave a positive reaction (61.5 per cent.). The proportion is thus seen to be about the same in the two groups. Taking all mothers of hereditary syphilitic infants together, 57 per cent. gave a positive reaction, and as recent observers state that in cases of latent syphilis a positive reaction is to be expected in 50 per cent., almost the same proportion, the authors take this to indicate that the mothers have really had syphilis themselves. The theory that the reaction products which produce complement fixation have been absorbed by the mother from the fetus, through the placenta, without the mother herself suffering from the disease, is discarded, because in many of the authors' cases the mothers had borne syphilitic children a good number of years previously, and yet showed complement fixation. That this could occur without the mother herself having suffered from the disease is a theory not upheld by analogy with any other infectious disease. A comparison between the results obtained by Wassermann's test in mother and child is promised when observations have been instituted in a larger number of cases than at present.

AN EPITOME OF CURRENT MEDICAL LITERATURE.

MEDICINE.

133. The Results of Cerebro-spinal Meningitis.

EPIDEMIC cerebro-spinal meningitis offers the best prognosis *quoad vitum* of all the forms of meningitis, but the exact prognosis *quoad restitutionem* has not yet been clearly made out. L. Cohn discusses the experience which he has made in Posen in a series of 82 cases, and collects the available evidence, which can be utilized to form a basis of prognosis with regard to the ultimate condition of the recovered patients (*Berl. klin. Woch.*, January 11th, 1909). Fifty patients died, and of the remaining 32, 3 were lost sight of and 2 died after leaving the hospital. There were therefore 27 cases which he could deal with. He calls attention to the pathology of the disease. Beginning with a hyperaemia of the meninges, a fibrinous purulent exudation is formed in the arachnoid and pia mater, the inflammation then spreads on to the grey substance and sero-fibrinous or purulent fluid collects in the ventricles. When the disease resolves, the pus cells disintegrate and the fluid becomes partly absorbed and partly organized, leaving behind a thickening of the arachnoid and pia with adhesions. The fluid in the ventricles may either be completely absorbed or a chronic hydrocephalus may result. Even extremely severe cases may terminate in almost complete pathological recovery. He cites a case in which the only residue left after a very bad attack was deafness. The child died of myocarditis complicating diphtheria a year later, and the *post-mortem* examination revealed some adhesions of the meninges and the bone in the site of the anterior fontanelle, but otherwise no macroscopical changes at all. The 27 cases may be divided into 8 mild cases, 15 medium cases, and 4 severe ones. In the mild cases the recovery was complete. The examination undertaken after recovery failed to reveal any abnormal sign. The intelligence was good and the children were holding their own at school. Some of the patients belonging to the medium cases recovered completely. In 2 cases paralysis of the extremities and of the ocular muscles were present when the patients were discharged, but disappeared completely at a later date. In 4 of the cases permanent symptoms were met with. Headache, especially after exertion such as bearing down or stooping, was complained of. Weakness of the arms and legs, which prevented the persons from performing any exercises involving the expenditure of exertion, was seen in 3. Loss of memory was complained of by 3 of the patients, while in 2 there was distinct loss of power of concentration and attention. Of the 4 patients belonging to the class of severe cases the child who died of myocarditis was one; 2 further patients were deaf on recovery; in both of them there was paralysis of the facial nerve; in one there was besides paralysis of the right arm; the paralytic symptoms cleared up completely, but the deafness persisted. The last case may be described as one of extreme severity, and the clinical history and description of the child after recovery admits of the possibility of a complete *restitutio ad integrum*. The author further records that agglutination with Weichselbaum's meningococci was found to be positive after more than two years in 2 cases.

140. Physical Causes of Cardiac Murmurs.

BRADSHAW (*Arch. des Mal. du Cœur, des Vaisseaux, et du Sang*, June, 1908) thinks that the view that valvular murmurs are due to a vibration of the valves caused by friction between the blood current and the valve is one which it is very difficult to uphold. In the first place, Poiseville has shown that there does not occur any friction at the valve. The theory that the murmur is due to vibrations of the blood is based upon the fact that when a liquid passes from a narrow into a larger space there is produced at this region a fluid vein. If one listens with a binaural stethoscope, whose upper opening is closed by a tightly stretched rubber membrane over a rubber tube connected with a stream of water, one finds that with moderate rapidity of flow of water, no sound is heard, provided the tube is of uniform calibre throughout its length; if, however, the tube be narrowed by pressing between thumb and finger, a sound resembling a cardiac murmur is heard; if the constriction is marked and the stream of water

strong, the hand feels a well-marked thrill. Careful examination further shows that the most marked vibrations occur, not at the point of constriction, but just beyond, and that these vibrations are felt for a considerable distance further on. The sound is heard for a certain distance above the constriction, but the thrill is not propagated on this side of the constriction, except under special circumstances. This experiment further shows that the sound is due to vibration of the fluid vein inside the tube, and not to vibrations of the edges of the constriction. If this explanation be accepted, one can readily understand the localization of the majority of valvular murmurs, the systolic murmur of mitral regurgitation, however, being an exception. According to the above view, this murmur ought to be best heard over the left auricle, and not, as every one agrees it is, at the apex beat of the heart, and to explain this the author puts forward the views of Petit, Fye-Smith, and Sanson, none of which he thinks are sufficiently explanatory. His own explanation is summed up as follows: The extremity of the cone formed by the mitral flaps is situated midway between the apex of the heart and the insertion of the flaps, and this cone, as Noel Paton has shown, is always filled with blood. In mitral insufficiency the pathological sluice is found about the extremity of the cone, and a fluid vein will therefore arise at the middle of this cone in the blood which fills it. The cone of blood surrounding this fluid vein will be put into vibrations, which vibrations will be conducted to the valves (representing the walls of the rubber tube in the experiment already described). These valves being, however, very thin, offer little or no resistance to the transmission of vibrations, which, traversing the valves, propagate themselves to the blood in the interior of the left ventricle surrounding the cone. Reflection of the vibrations to the walls of the cavity then occurs, the whole mass of blood in the ventricle will be brought to vibrate uniformly, and this vibration will be conducted especially to the apex, since at this part the muscular wall is thinner than at others, and because this part is nearest to the thoracic wall. In fact, the vibrations which arise in the fluid vein are conducted to the apex of the heart by the blood, this being rendered possible by the anatomical disposition of the valves.

141

Raynaud's Disease.

SACHS (*Amer. Journ. of Med. Sciences*, October, 1908) regards Raynaud's disease, erythromelalgia, and allied conditions as far more often the expression of disease of the peripheral blood vessels than associated with central nervous disease, Raynaud's disease being a pure angi-neurosis, either occurring as an independent form of disease or in association with some central nervous affection. From observations upon an unusually large number of such cases it is probable that malnutrition, premature arterio-sclerosis, and occupations involving a retardation of the venous circulation—for example, tailoring, sewing-machine work, etc.—largely enter into the etiology; and, although a large number may be due to syphilis, it would seem that the rest in bed, with elevation of the foot, application of heat, etc., by improving the return circulation, does more to improve the condition than can be brought about by severe antisyphilitic treatment. Pathologically, marked interference with the peripheral blood supply is present in all classes of cases, and their study has drawn attention to the importance of routine examination of the dorsal artery of the foot. Raynaud's disease and erythromelalgia are often associated with one another, the types blending so readily that any marked line of demarcation cannot always be drawn. Clinically, the disease may at one point correspond closely with the erythromelalgic type, and later with the Raynaud type, erythromelalgia being relatively frequently associated with dry gangrene. Cases occur also which at the outset are typical of Raynaud's disease, but later might well be designated cases of spontaneous gangrene due to obliterating endarteritis. Occasionally Raynaud's disease is associated with chronic rheumatism, and with cases of cerebral endarteritis, and attention is called to the association also of intermittent claudication with symptoms of the disease. Notes of 6 cases are given typifying the points to which attention is directed.

SURGERY.

142. Suture of the Lung for Severe Haemorrhage.

LOTSCH publishes the details of two cases of suture of the lung, performed for bleeding which threatened the life of the patient (*Munch. med. Woch.*, January 19th, 1909). The first patient was a workman, aged 26, who was stabbed with a knife in the left side of the back. The extreme pallor of the face, etc., the soft, small, rapid pulse, and the physical signs pointed to bleeding into the left pleural cavity. The chest was opened in Brauer's plus pressure chamber, and on increasing the pressure to 17 cm. about 1½ litres of blood escaped. The wound in the lung was found and closed with catgut sutures. Saline infusion was given after the operation, and the pulse improved. The recovery was disturbed by a purulent effusion into the pleura which proved to be sterile, while fibrolysin injections were given to prevent contraction of the pleural adhesions during healing of the empyema. He was discharged well. The second patient attempted to commit suicide by shooting himself twice through the chest. The clinical diagnosis was wound of the left lung, haemopneumothorax, and possibly wound in the heart. At the operation a large quantity of blood was evacuated from the pleura, and, after the field of operation was clear, the two shot wounds were found and sutured. This patient also got an empyema, but with suitable treatment complete healing took place, and the man was almost well when discharged. The shots were not found at the operation, but were seen after Roentgen examination. In discussing the cases Lotsch justifies his procedure by showing that over 40 per cent. of such cases die if treated expectantly. The difficult question to decide is when is a pulmonary haemorrhage abundant. He was guided by the degree of anaemia. He discusses the technique of the operation, and also adds a few words on the treatment of secondary empyema, which appears to be common after intrathoracic operations.

143. Uretero-Intestinal Anastomosis after Total Cystectomy.

LEGUEU (*Bull. et Mém. de la Soc. de Chir. de Paris*, No. 33, 1908), in a report on a case of total cystectomy for bleeding tumours, communicated by Marion, after dealing with the indications for extirpation of the bladder, discusses the difficult question of what to do with the ureters. To leave the open ends in the wound is, as is proved by the fatal result of Marion's case, to court disaster, and the attempts to overcome the difficulty by attaching them to the skin or to the wall of the vagina have failed. Uretero-rectal anastomosis becomes a very serious procedure when both ureters have been divided, as it has recently been shown by Papin that such a course has been followed by 16 deaths in 19 cases of total cystectomy. In some of these cases the fatal result occurred soon after the operation, while in others it was delayed for some months and was due to pyelonephritis and pyonephrosis. Legueu suggests that it might be better to practise double nephrostomy; but to those surgeons who would hesitate to subject by such treatment their patients to very serious infirmity, and who decide on discharging the urine into the intestine, he would propose that the double implantation be effected in two stages with an interval of some few days. In a discussion of Legueu's report it was held by Tuffier that the late evils of uretero-intestinal implantation originate in stenosis of the distal ends of the ureters and in consequent urinary stagnation and renal infection. By preserving a collar of vesical mucous membrane, and, if possible, of the whole thickness of the wall of the bladder, at the end of each of the detached ureters, and by suturing this to the margins of the opening in the intestine, the risks of ascending infection, it is held, may be diminished.

144. Metastases of Glioma Retinae.

It is quite a common thing for a malignant glioma to involve the extraorbital structures of the face and head, but secondary growths in distant parts of the body are infrequent. Wintersteiner (*Das Neuroepithelioma Retinae*, Wien, 1897) collected 497 cases of glioma. In 46 cases the adjacent lymph glands were affected: in 43 the brain and meninges; in 40 the cranium and face bones; in 9 the parotid gland. The metastatic growths were fewer: the skeletal bones in 9 cases: the liver in 7, the ovary and kidney in 2; the lungs and spleen 1 each. Fehn (*Centralbl. für prakt. Augenheilk.*, 1900, xxiv, 129) reports a case with metastatic growths in the liver, the inguinal glands, the ribs, and the mediastinum. Radcliffe and Goldberg (*Arch. of Ophthalm.*, 1907, xxxvi, p. 223) found secondary

hepatic tumours: J. P. Gardiner (*Arch. of Ophthalm.*, xxxvii, p. 657, November, 1908) collects these cases, and gives a detailed account of one of his own which is illustrated by plates, showing the head with recurrent growths in each eye, and the histology of the primary glioma and its metastasis. The skull and meninges were extensively involved, with the bones adjacent to the orbit, the cervical glands, the ribs, the vertebrae, the spinal canal and dura, the testicle, the os ilei, the pubes, the ischia, the long bones of the leg, and the manubrium. In short there was general and extensive dissemination of the glioma.

145. Early Orthopaedic Treatment in Poliomyelitis.
